

2022 ESC Guidelines on cardiovascular assessment and management of patients undergoing non-cardiac surgery

Developed by the task force for cardiovascular assessment and management of patients undergoing non-cardiac surgery of the European Society of Cardiology (ESC)

Endorsed by the European Society of Anaesthesiology and Intensive Care (ESAIC)

Authors/Task Force Members: Sigrun Halvorsen ^{*†} (Chairperson) (Norway), Julinda Mehilli ^{*†} (Chairperson) (Germany), Salvatore Cassese^{**} (Task Force Coordinator) (Germany), Trygve S. Hall^{**} (Task Force Coordinator) (Norway), Magdy Abdelhamid (Egypt), Emanuele Barbato (Italy/Belgium), Stefan De Hert¹ (Belgium), Ingrid de Laval (Sweden), Tobias Geisler (Germany), Lynne Hinterbuchner (Austria), Borja Ibanez (Spain), Radosław Lenarczyk (Poland), Ulrich R. Mansmann (Germany), Paul McGreavy (United Kingdom), Christian Mueller (Switzerland), Claudio Muneretto (Italy), Alexander Niessner (Austria), Tatjana S. Potpara (Serbia), Arsen Ristić (Serbia), L. Elif Sade (United States of America/Turkey), Henrik Schirmer (Norway), Stefanie Schüpke (Germany), Henrik Sillesen (Denmark), Helge Skulstad (Norway), Lucia Torracca (Italy), Oktay Tutarel (Germany), Peter Van Der Meer (Netherlands), Wojtek Wojakowski (Poland), Kai Zacharowski¹ (Germany), and ESC Scientific Document Group

* Corresponding authors: Sigrun Halvorsen, Department of Cardiology, Oslo University Hospital Ullevål, Oslo, Norway, and University of Oslo, Oslo, Norway. Tel.: +47 91317460. E-mail: sigrun.halvorsen@medisin.uio.no.

Julinda Mehilli, Department: Medizinische Klinik I, Landshut-Achdorf Hospital, Landshut, Germany, Klinikum der Universität München, Ludwig-Maximilians-Universität and German Centre for Cardiovascular Research (DZHK), partner site Munich Heart Alliance, Munich, Germany. Tel.: +49 871 4042782. E-mail: Julinda.mehilli@lakumed.de

[†] The two chairpersons contributed equally to the document and are joint corresponding authors.

^{**} The two Task Force Coordinators contributed equally to the document

Author/Task Force Member affiliations: listed in author information.

¹Representing the European Society of Anaesthesiology and Intensive Care (ESAIC)

ESC Clinical Practice Guidelines (CPG) Committee listed in the Appendix.

ESC subspecialty communities having participated in the development of this document:

Associations: Association for Acute CardioVascular Care (ACVC), Association of Cardiovascular Nursing & Allied Professions (ACNAP), European Association of Cardiovascular Imaging (EACVI), European Association of Percutaneous Cardiovascular Interventions (EAPCI), European Heart Rhythm Association (EHRA), and Heart Failure Association (HFA).

Councils: Council of Cardio-Oncology and Council on Valvular Heart Disease.

Working Groups: Adult Congenital Heart Disease, Aorta and Peripheral Vascular Diseases, Cardiovascular Pharmacotherapy, Cardiovascular Surgery, and Thrombosis.

Patient Forum

The content of these European Society of Cardiology (ESC) Guidelines has been published for personal and educational use only. No commercial use is authorized. No part of the ESC Guidelines may be translated or reproduced in any form without written permission from the ESC. Permission can be obtained upon submission of a written request to Oxford University Press, the publisher of the *European Heart Journal*, and the party authorized to handle such permissions on behalf of the ESC (journals.permissions@oup.com).

Document-Reviewers: Juhani Knuuti, (CPG Review Coordinator) (Finland), Steen Dalby Kristensen, (CPG Review Coordinator) (Denmark), Victor Aboyans (France), Ingo Ahrens (Germany), Sotiris Antoniou (United Kingdom), Riccardo Asteggiano (Italy), Dan Atar (Norway), Andreas Baumbach (United Kingdom), Helmut Baumgartner (Germany), Michael Böhm (Germany), Michael A. Borger (Germany), Hector Bueno (Spain), Jelen Čelutkienė (Lithuania), Alaide Chieffo (Italy), Maya Cikes (Croatia), Harald Darius (Germany), Victoria Delgado (Spain), Philip J. Devereaux (Canada), David Duncker (Germany), Volkmar Falk (Germany), Laurent Fauchier (France), Gilbert Habib (France), David Hasdai (Israel), Kurt Huber (Austria), Bernard Iung (France), Tiny Jaarsma (Sweden), Aleksandra Konradi (Russian Federation), Konstantinos C. Koskinas (Switzerland), Dipak Kotecha (United Kingdom), Ulf Landmesser (Germany), Basil S. Lewis (Israel), Ales Linhart (Czech Republic), Maja-Lisa Løchen (Norway), Michael Maeng (Denmark), Stéphane Manzo-Silberman (France), Richard Mindham (United Kingdom), Lis Neubeck (United Kingdom), Jens Cosedis Nielsen (Denmark), Steffen E. Petersen (United Kingdom), Eva Prescott (Denmark), Amina Rakisheva (Kazakhstan), Antti Saraste (Finland), Dirk Sibbing (Germany), Jolanta Siller-Matula (Austria), Marta Sitges (Spain), Ivan Stankovic (Serbia), Rob F. Storey (United Kingdom), Jurrien ten Berg (Netherlands), Matthias Thielmann (Germany), and Rhian M. Touyz (Canada/United Kingdom)

All experts involved in the development of these guidelines have submitted declarations of interest. These have been compiled in a report and simultaneously published in a supplementary document to the guidelines. The report is also available on the ESC website www.escardio.org/Guidelines

SD See the *European Heart Journal* online for supplementary data that include background information and detailed discussion of the data that have provided the basis of the guidelines.

Keywords

Guidelines • Non-cardiac surgery • Pre-operative cardiac risk assessment • Pre-operative cardiac testing • Biomarkers • Pre-operative coronary artery revascularization • Peri-operative cardiac management • Anti-thrombotic therapy • Peri-operative beta-blockers • Pre-operative treatment of valvular disease • Peri-operative treatment of arrhythmias • Post-operative cardiac surveillance • Peri-operative myocardial injury/infarction

Table of contents

1. Preamble	7	3.2.1.1. Vascular and endovascular procedures	18
2. Introduction	9	3.2.1.2. Video-assisted non-cardiac surgery	18
2.1. What is new	9	3.3. Patient-related risk	18
2.2. The magnitude of the problem	14	3.3.1. Initial assessment	18
2.3. Change in demographics	15	3.3.1.1. Patients aged <65 years without a history of	
2.4. Purpose	15	cardiovascular disease or cardiovascular risk factors	18
2.5. The outcomes we want to prevent	16	3.3.1.2. Patients aged ≥65 years or with cardiovascular risk	
3. Clinical risk evaluation	16	factors	18
3.1. Surgery-related risk	16	3.3.1.3. Patients with established cardiovascular disease	19
3.1.1. Timing of surgery	17	3.3.2. Patients with murmurs, chest pain, dyspnoea, or	
3.2. Type of surgical approach	17	peripheral oedema	20
3.2.1. Laparoscopy	17	3.3.2.1. Murmurs	20
		3.3.2.2. Chest pain	20
		3.3.2.3. Dyspnoea	20

Disclaimer: The ESC Guidelines represent the views of the ESC and were produced after careful consideration of the scientific and medical knowledge and the evidence available at the time of their publication. The ESC is not responsible in the event of any contradiction, discrepancy, and/or ambiguity between the ESC Guidelines and any other official recommendations or guidelines issued by the relevant public health authorities, particularly in relation to good use of health care or therapeutic strategies. Health professionals are encouraged to take the ESC Guidelines fully into account when exercising their clinical judgment, and in the determination and the implementation of preventive, diagnostic, or therapeutic medical strategies; however, the ESC Guidelines do not override, in any way whatsoever, the individual responsibility of health professionals to make appropriate and accurate decisions in consideration of each patient's health condition and in consultation with that patient and, where appropriate and/or necessary, the patient's caregiver. The ESC Guidelines do not exempt health professionals from taking into full and careful consideration the relevant official updated recommendations or guidelines issued by the competent public health authorities, in order to manage each patient's case in light of the scientifically accepted data pursuant to their respective ethical and professional obligations. It is also the health professional's responsibility to verify the applicable rules and regulations relating to drugs and medical devices at the time of prescription.

3.3.2.4. Peripheral oedema	20	5.3.2.2.6. When to restart non-vitamin K antagonist oral anticoagulants after interventions	43
3.4. Timing of adequate risk evaluation	21	5.3.2.3. Combination therapy (antiplatelet and anticoagulant)	43
3.5. Avoidance or allowance for surgery in the individual patient	21	5.4. Peri-operative thromboprophylaxis	44
3.6. The patient perspective	21	5.5. Patient blood management	44
4. Pre-operative assessment tools	22	5.5.1. Pre-operative anaemia—diagnosis and treatment	45
4.1. Risk scores	22	5.5.2. Bleeding and reduction of iatrogenic diagnostic/ surgery-related blood loss	45
4.1.1. General risk calculators	22	5.5.3. Optimal blood component use with patient-centred clinical decision support	46
4.1.2. Frailty	24	6. Specific diseases	46
4.2. Functional capacity	24	6.1. Coronary artery disease	46
4.3. Electrocardiography	25	6.1.1. Risk for patients with coronary artery disease	46
4.4. Biomarkers	25	6.1.2. Pre-operative risk assessment and management	47
4.5. Non-invasive and invasive procedures	26	6.1.3. Revascularization strategies	47
4.5.1. Resting transthoracic echocardiography	26	6.1.3.1. Chronic coronary syndromes	47
4.5.2. Stress tests	27	6.1.3.2. Acute coronary syndromes	47
4.5.2.1. Exercise stress test	27	6.2. Chronic heart failure	49
4.5.2.2. Stress imaging	27	6.2.1. Risk for patients with heart failure	49
4.5.3. Angiography	28	6.2.2. Pre- and post-operative management strategies	49
4.5.3.1. Coronary computed tomography angiography	28	6.2.3. Hypertrophic obstructive cardiomyopathy	50
4.5.3.2. Invasive coronary angiography	28	6.2.4. Patients with ventricular assist devices undergoing non-cardiac surgery	50
5. General risk-reduction strategies	29	6.3. Valvular heart disease	50
5.1. Cardiovascular risk factors and lifestyle interventions	29	6.3.1. Risk for patients with valvular heart disease	50
5.2. Pharmacological	29	6.3.2. Pre-operative management strategies and risk- reduction strategy	51
5.2.1. Beta-blockers	29	6.3.2.1. Aortic valve stenosis	51
5.2.2. Amiodarone	30	6.3.2.2. Mitral valve stenosis	52
5.2.3. Statins	30	6.3.2.3. Aortic valve regurgitation	53
5.2.4. Renin–angiotensin–aldosterone system inhibitors	30	6.3.2.4. Mitral valve regurgitation	53
5.2.5. Calcium channel blockers	30	6.3.2.5. Patients with prosthetic valve(s)	53
5.2.6. Alpha-2 receptor agonists	31	6.3.2.6. Prophylaxis of infective endocarditis	53
5.2.7. Diuretics	31	6.4. Known or newly diagnosed arrhythmias	54
5.2.8. Ivabradine	31	6.4.1. Peri-operative management—general measures	54
5.2.9. Sodium–glucose co-transporter-2 inhibitors	31	6.4.2. Supraventricular arrhythmias	54
5.3. Peri-operative handling of antithrombotic agents	32	6.4.3. Atrial fibrillation/flutter	54
5.3.1. Antiplatelets	32	6.4.4. Ventricular arrhythmias	54
5.3.1.1. Single antiplatelet therapy	32	6.4.5. Bradyarrhythmias	56
5.3.1.2. Dual antiplatelet therapy	35	6.4.6. Management of patients with cardiac implantable electronic devices	56
5.3.1.3. De-escalation of antiplatelet effect	37	6.5. Adult congenital heart disease	57
5.3.1.4. Platelet function guided peri-operative management of antiplatelet therapy	37	6.6. Pericardial diseases	58
5.3.2. Oral anticoagulants	38	6.7. Pulmonary disease and pulmonary arterial hypertension	59
5.3.2.1. Vitamin K antagonists	38	6.7.1. Pulmonary disease	59
5.3.2.1.1. Vitamin K antagonists in patients with mechanical heart valves	38	6.7.2. Pulmonary arterial hypertension	59
5.3.2.1.2. Vitamin K antagonists for atrial fibrillation/ venous thromboembolism	39	6.8. Arterial hypertension	60
5.3.2.1.3. Restarting vitamin K antagonists after invasive procedures or surgery	39	6.9. Peripheral artery disease	61
5.3.2.1.4. Reversal of vitamin K antagonists	39	6.9.1. Peripheral artery disease and non-vascular non-cardiac surgery	61
5.3.2.2. Non-vitamin K antagonist oral anticoagulants	39	6.9.2. Peripheral artery disease and vascular non-cardiac surgery	61
5.3.2.2.1. Unplanned surgery in patients on non-vitamin K antagonist oral anticoagulants and reversal for emergency procedures	39	6.10. Cerebrovascular disease	62
5.3.2.2.2. Planned interventions in patients on non- vitamin K oral anticoagulants	41	6.11. Renal disease	62
5.3.2.2.3. Bridging	41	6.12. Obesity	63
5.3.2.2.4. Laboratory testing before surgery	41		
5.3.2.2.5. Considerations for specific procedures	42

Abbreviations and acronyms

AAA	Abdominal aortic aneurysm
AAD	Antiarrhythmic drug
ACEI	Angiotensin-converting-enzyme inhibitor
ACHD	Adults with congenital heart disease
ACS	Acute coronary syndrome
ACS NSQIP	American College of Surgery National Surgical Quality Improvement Program
AF	Atrial fibrillation
AKI	Acute kidney injury
aPTT	Activated partial thromboplastin time
AR	Aortic valve regurgitation
ARB	Angiotensin receptor blocker
ARNI	Angiotensin receptor neprilysin inhibitor
AS	Aortic valve stenosis
ASA	Acetylsalicylic acid
ASA-PS	American Society of Anesthesiology Physical Status
ASCVD	Atherosclerotic cardiovascular disease
AUB-HAS2	American University of Beirut (AUB)-HAS2
AUC	Area under curve
AVR	Aortic valve replacement
BAV	Balloon aortic valvuloplasty
BCSH	British Committee for Standards in Haematology
<i>b.i.d.</i>	<i>Bis in die</i> (twice a day)
BTKi	Bruton tyrosine kinase inhibitors

BMI	Body mass index	ECG	Electrocardiographic/electrocardiogram
BMS	Bare metal stent	EDKA	Euglycaemic diabetic ketoacidosis
BNP	B-type natriuretic peptide	eGFR	Estimated glomerular filtration rate
BP	Blood pressure	EMI	Electromagnetic interference
b.p.m.	Beats per minute	EORP	EURObservational Research Programme
BSA	Body surface area	ESA	European Society of Anaesthesiology
CABG	Coronary artery bypass graft	ESC	European Society of Cardiology
CAD	Coronary artery disease	ESH	European Society of Hypertension
CARP	Coronary Artery Revascularization Prophylaxis (trial)	ESTS	European Society of Thoracic Surgeons
CAS	Carotid artery stenting	ESVS	European Society for Vascular Surgery
CASS	Coronary Artery Surgery Study	EuSOS	European Surgical Outcomes Study
CCB	Calcium channel blocker	EVAR	Endovascular abdominal aortic aneurysm repair
CCS	Chronic coronary syndrome	FDA	US Food and Drug Administration
CCTA	Coronary computed tomography angiography	FFR	Fractional flow reserve
CEA	Carotid endarterectomy	FIIa	Factor IIa
CHA ₂ DS ₂ -VASc	Congestive heart failure, hypertension, age ≥ 75 years, diabetes mellitus, stroke, vascular disease, age 65–74 years, sex category (female)	FOCUS	Focused cardiac ultrasound
CI	Confidence interval	FXa	Factor Xa
CIED	Cardiac implantable electronic device	GDMT	Guideline-directed medical therapy
CK	Creatinine kinase	GFR	Glomerular filtration rate
CKD	Chronic kidney disease	HbA1c	Glycated haemoglobin
CKD-EPI	Chronic Kidney Disease Epidemiology Collaboration	HF	Heart failure
C ^{max}	Maximum serum concentration	HIP-ATTACK	HIP Fracture Accelerated Surgical Treatment And Care track (trial)
CMR	Cardiac magnetic resonance	HR	Hazard ratio
COAPT	Cardiovascular Outcomes Assessment of the MitraClip Percutaneous Therapy for Heart Failure Patients with Functional Mitral Regurgitation (trial)	hs-cTn	High-sensitivity cardiac troponin
COPD	Chronic obstructive pulmonary disease	i.v.	Intravenous
CORIDA	Per-procedural Concentration of Direct Oral Anticoagulants (trial)	ICA	Invasive coronary angiography
Coronary CTA VISION	Coronary Computed Tomographic Angiography and Vascular Events in Noncardiac Surgery Patients Cohort Evaluation (trial)	ICD	Implantable cardioverter–defibrillator
COVID-19	Coronavirus disease 2019	ICU	Intensive care unit
CPET	Cardiopulmonary exercise testing	ID	Iron deficiency
CRF	Cardiorespiratory fitness	IHD	Ischaemic heart disease
CRT	Cardiac resynchronization therapy	INR	International normalized ratio
CT	Computed tomography	ISCHEMIA	International Study of Comparative Health Effectiveness with Medical and Invasive Approaches (trial)
cTn T/I	Cardiac troponin T/I	iwFR	Instantaneous wave-free ratio
CTO	Chronic total occlusion	KDIGO	Kidney Disease: Improving Global Outcomes
CV	Cardiovascular	LD	Loading dose
CVD	Cardiovascular disease	LMWH	Low molecular weight heparin
DAPT	Dual antiplatelet therapy	LOAD	Lowering the Risk of Operative Complications Using Atorvastatin Loading Dose (trial)
DASI	Duke Activity Status Index	LoE	Level of evidence
DES	Drug-eluting stent	LV	Left ventricular
DM	Diabetes mellitus	LVEF	Left ventricular ejection fraction
DSE	Dobutamine stress echocardiography	LVESD	Left ventricular end-systolic diameter
dTT	Diluted thrombin time	LVESDi	Left ventricular end-systolic dimension index
EACTS	European Association for Cardio-Thoracic Surgery	MACE	Major adverse cardiovascular event
		MET	Metabolic equivalent
		METS	Measurement of Exercise Tolerance before Surgery (trial)
		MHV	Mechanical heart valve

MI	Myocardial infarction	TIA	Transient ischaemic attack
MINIS	Myocardial injury following non-cardiac surgery	TTE	Transthoracic echocardiography
MR	Mitral valve regurgitation	UFH	Unfractionated heparin
MS	Mitral valve stenosis	ULN	Upper limit of normal
NCS	Non-cardiac surgery	VAD	Ventricular assist device
NOAC	Non-vitamin K antagonist oral anticoagulant	VATS	Video-assisted thoracic surgery
NSAID	Non-steroidal anti-inflammatory drug	VEGF _i	Vascular endothelial growth factor inhibitor
NSTE-ACS	Non-ST-segment elevation acute coronary syndrome	VF	Ventricular fibrillation
NT-proBNP	N-terminal pro-B-type natriuretic peptide	VHD	Valvular heart disease
NYHA	New York Heart Association	VISION	Vascular Events in Noncardiac Surgery Patients Cohort Evaluation (trial)
OAC	Oral anticoagulant	VKA	Vitamin K antagonist
<i>o.d.</i>	<i>Omnis die</i> (once a day)	VKORC1	Vitamin K epoxide reductase complex 1
OR	Odds ratio	VO ₂	Oxygen consumption
OSA	Obstructive sleep apnoea	VT	Ventricular tachycardia
PA	Pulmonary artery	VTE	Venous thromboembolism
PAD	Peripheral artery disease	WHA	World Health Assembly
PAH	Pulmonary arterial hypertension	WPW	Wolff–Parkinson–White
PAUSE	Perioperative Anticoagulant Use for Surgery Evaluation (trial)		
PBM	Patient Blood Management		
PCC	Prothrombin complex concentrate		
PCI	Percutaneous coronary intervention		
PE	Pulmonary embolism		
PMC	Percutaneous mitral commissurotomy		
PMI	Peri-operative myocardial infarction/ injury		
POISE	PeriOperative ISchemic Evaluation Trial		
PPC	Prothrombin complex concentrate		
PT	Prothrombin time		
PVC	Premature ventricular contractions		
QI	Quality indicator		
RAAS	Renin–angiotensin–aldosterone system		
RBC	Red blood cell		
RCRI	Revised Cardiac Risk Index		
RCT	Randomized controlled trial		
RF	Radiofrequency		
rHuEPO	Recombinant human erythropoietin		
RR	Relative risk		
RV	Right ventricular		
SAPT	Single antiplatelet therapy		
SARS-CoV-2	Severe acute respiratory syndrome coronavirus 2		
SAVR	Surgical aortic valve replacement		
SCD	Sudden cardiac death		
SGLT-2	Sodium–glucose co-transporter-2		
SORT	Surgical Outcome Risk Tool		
SPAP	Systolic pulmonary artery pressure		
STEMI	ST-segment elevation myocardial infarction		
SVT	Supraventricular tachycardia		
TAVI	Transcatheter aortic valve implantation		
TEE	Transoesophageal echocardiography		
TEER	Transcatheter edge-to-edge repair		

1. Preamble

Guidelines summarize and evaluate available evidence, with the aim of assisting health professionals in proposing the best management strategies for an individual patient with a given condition. Guidelines and their recommendations should facilitate decision-making of health professionals in their daily practice. Guidelines, however, are not a substitute for the patient's relationship with their practitioner. The final decisions concerning an individual patient must be made by the responsible health professional(s), based on what they consider to be the most appropriate in the circumstances. These decisions are made in consultation with the patient and caregiver as appropriate.

Guidelines are intended for use by health professionals. To ensure that all users have access to the most recent recommendations, the European Society of Cardiology (ESC) makes its guidelines freely available. The ESC warns readers that the technical language may be misinterpreted and declines any responsibility in this respect.

Many guidelines have been issued in recent years by the ESC. Because of their impact on clinical practice, quality criteria for the development of guidelines have been established in order to make all decisions transparent to the user. The recommendations for formulating and issuing ESC Guidelines can be found on the ESC website (<https://www.escardio.org/Guidelines>). The ESC Guidelines represent the official position of the ESC on a given topic and are regularly updated.

In addition to the publication of Clinical Practice Guidelines, the ESC carries out the EURObservational Research Programme of international registries of cardiovascular diseases and interventions, which are essential to assess diagnostic/therapeutic processes, use of resources, and adherence to guidelines. These registries aim to provide a better understanding of medical practice in Europe and around the world, and are based on high-quality data collected during routine clinical practice. Furthermore, the ESC develops sets of quality indicators (QIs)—which are tools to evaluate the level of implementation of the guidelines and may be used by the ESC, hospitals, healthcare providers, and

professionals to measure clinical practice, and in educational programmes—alongside the key messages from the guidelines, to improve quality of care and clinical outcomes.

The members of this Task Force were selected by the ESC to represent professionals involved with the medical care of patients with this pathology. The selection procedure aimed to ensure that there is a representative mix of members, predominantly from across the whole of the ESC region and from relevant ESC Subspecialty Communities. Consideration was given to diversity and inclusion, notably with respect to gender and country of origin. A critical evaluation of diagnostic and therapeutic procedures was performed, including assessment of the risk–benefit ratio. The level of evidence and the strength of the recommendation of particular management

options were weighed and scored according to pre-defined scales, as outlined below. The Task Force followed the ESC voting procedures. All recommendations subject to a vote achieved at least 75% among voting members.

The experts of the writing and reviewing panels provided declaration of interest forms for all relationships that might be perceived as real or potential sources of conflicts of interest. Their declarations of interest were reviewed according to the ESC declaration of interest rules and can be found on the ESC website (<http://www.escardio.org/Guidelines>) and have been compiled in a report and simultaneously published in a supplementary document to the guidelines. This process ensures transparency and prevents potential biases in the development and review processes. Any changes in declarations of

Table 1 Classes of recommendations

Classes of recommendations	Definition		Wording to use
	Class I	Evidence and/or general agreement that a given treatment or procedure is beneficial, useful, effective.	Is recommended or is indicated
	Class II	Conflicting evidence and/or a divergence of opinion about the usefulness/efficacy of the given treatment or procedure.	
	Class IIa	Weight of evidence/opinion is in favour of usefulness/efficacy.	Should be considered
	Class IIb	Usefulness/efficacy is less well established by evidence/opinion.	May be considered
	Class III	Evidence or general agreement that the given treatment or procedure is not useful/effective, and in some cases may be harmful.	Is not recommended

©ESC 2022

Table 2 Levels of evidence

Level of evidence A	Data derived from multiple randomized clinical trials or meta-analyses.
Level of evidence B	Data derived from a single randomized clinical trial or large non-randomized studies.
Level of evidence C	Consensus of opinion of the experts and/or small studies, retrospective studies, registries.

©ESC 2022

interest that arose during the writing period were notified to the ESC and updated. The Task Force received its entire financial support from the ESC without any involvement from the healthcare industry.

The ESC CPG Committee supervises and coordinates the preparation of new guidelines. The Committee is also responsible for the approval process of these guidelines. The ESC Guidelines undergo extensive review by the CPG Committee and external experts, including a mix of members from across the whole of the ESC region and from relevant ESC Subspecialty Communities and National Cardiac Societies. After appropriate revisions, the guidelines are signed-off by all the experts involved in the Task Force. The finalized document is signed-off by the CPG Committee for publication in the *European Heart Journal*. The guidelines are developed after careful consideration of the scientific and medical knowledge and the evidence available at the time of their writing.

The task of developing the ESC Guidelines also includes creating educational tools and implementing programmes for the recommendations, including condensed pocket guidelines versions, summary slides, summary cards for non-specialists, and an electronic version for digital applications (smartphones, etc.). These versions are abridged and thus, for more detailed information, the user should always access the full text version of the guidelines, which is freely available via the ESC website and the *European Heart Journal*. The National Cardiac Societies of the ESC are encouraged to endorse, adopt, translate, and implement all ESC Guidelines. Implementation programmes are needed because it has been shown that the outcome of disease may be favourably influenced by the thorough application of clinical recommendations.

Health professionals are encouraged to take the ESC Guidelines fully into account when exercising their clinical judgment, and in determining and implementing preventive, diagnostic, or therapeutic medical strategies. However, the ESC Guidelines do not override, in any way whatsoever, the individual responsibility of health professionals to make appropriate and accurate decisions in considering each patient's health condition and in consulting with that patient or the patient's caregiver where appropriate and/or necessary. It is also the health professional's responsibility to verify the rules and regulations applicable in each country to drugs and devices at the time of prescription and, where appropriate, to respect the ethical rules of their profession.

Off-label use of medication may be presented in these guidelines if a sufficient level of evidence shows that it can be considered medically appropriate to a given condition and if patients could benefit from the recommended therapy. However, the final decisions concerning an individual patient must be made by the responsible health professional, giving special consideration to:

- the specific situation of the patient. In this respect, it is specified that, unless otherwise provided for by national regulations, off-label use of medication should be limited to situations where it is in the patient's interest to do so, with regard to the quality, safety, and efficacy of care, and only after the patient has been informed and provided consent;
- and country-specific health regulations, indications by governmental drug regulatory agencies, and the ethical rules to which health professionals are subject, where applicable.

2. Introduction

2.1. What is new

Table 3 New concepts and sections in the current guidelines

A new flowchart for general assessment of patients before NCS.
A new section on pre-operative assessment of patients with newly detected murmurs, dyspnoea, oedema, or angina.
A new section on the patient perspective.
A new section on assessment of frailty.
A revised and expanded focus on use of biomarkers in NCS
A revised and expanded section on peri-operative management of antiplatelet therapy.
A revised and expanded section on peri-operative management of oral anticoagulants.
A new section on peri-operative thromboprophylaxis.
A dedicated section on patient blood management.
A new section on management of cardiovascular risk in patients with cancer undergoing NCS.
A small section on NCS in patients with recent COVID-19.
A new section on diagnosis and management of post-operative complications during NCS.

COVID-19, coronavirus 2019; NCS, non-cardiac surgery

Table 4 What is new

Table 4A New recommendations

Recommendation	Class
Clinical risk evaluation—Section 3	
Patients scheduled for NCS	
In all patients scheduled for NCS, an accurate history, and clinical examination are recommended.	I
It is recommended to perform a pre-operative risk assessment, ideally at the same time as the NCS is proposed.	I
If time allows, it is recommended to optimize guideline-recommended treatment of CVD and CV risk factors before NCS.	I
Endovascular or video-assisted procedures should be considered for patients with high CV risk undergoing vascular or pulmonary surgery.	IIa
Patients aged <65 years without signs, symptoms, or history of CVD	
In patients with a family history of genetic cardiomyopathy, it is recommended to perform an ECG and TTE before NCS, regardless of age and symptoms.	I
In patients aged 45–65 years without signs, symptoms, or history of CVD, ECG and biomarkers should be considered before high-risk NCS.	IIa

Continued

Pre-operative assessment in patients with a newly detected murmur, chest pain, dyspnoea, or peripheral oedema	
In patients with a newly detected murmur <i>and</i> symptoms or signs of CVD, TTE is recommended before NCS.	I
In patients with a newly detected murmur suggesting clinically significant pathology, TTE is recommended before high-risk NCS.	I
In patients with a newly detected murmur, but without other signs or symptoms of CVD, TTE should be considered before moderate and high-risk NCS.	IIa
If a patient scheduled for elective NCS has chest pain or other symptoms suggestive of undetected CAD, further diagnostic work-up before NCS is recommended.	I
If a patient in need of acute NCS also has chest pain or other symptoms suggestive of undetected CAD, a multidisciplinary assessment approach is recommended to choose the treatment with lowest total risk for the patient.	I
In patients with dyspnoea and/or peripheral oedema, an ECG and an NT-proBNP/BNP test is indicated before NCS, unless there is a certain non-cardiac explanation.	I
In patients with dyspnoea and/or peripheral oedema and elevated NT-proBNP/BNP, TTE is recommended before NCS.	I
Patient information	
It is recommended to give patients individualized instructions for pre-operative and post-operative changes in medication, in verbal and written formats with clear and concise directions.	I
It should be considered to set up a structured information list (e.g. a checklist to help with common issues) for patients with CVD or at high risk of CV complications scheduled for NCS.	IIa
Pre-operative assessment tools—Section 4	
Frailty and functional capacity	
In patients aged ≥ 70 years, being scheduled to undergo intermediate- or high-risk NCS, frailty screening should be considered using a validated screening tool.	IIa
Adjusting risk assessments according to self-reported ability to climb two flights of stairs should be considered in patients referred for intermediate- or high-risk NCS.	IIa
Transthoracic echocardiography	
TTE is recommended in patients with poor functional capacity and/or high NT-proBNP/BNP, or if murmurs are detected before high-risk NCS, in order to undertake risk-reduction strategies.	I
TTE should be considered in patients with suspected new CVD or unexplained signs or symptoms before high-risk NCS.	IIa
TTE may be considered in patients with poor functional capacity, abnormal ECG, high NT-proBNP/BNP, or ≥ 1 clinical risk factor before intermediate-risk NCS.	IIb
To avoid delaying surgery, a FOCUS exam performed by trained specialists may be considered as an alternative to TTE for pre-operative triage.	IIb
Stress imaging	
Stress imaging should be considered before high-risk NCS in asymptomatic patients with poor functional capacity, and previous PCI or CABG.	IIa

Continued

Coronary angiography	
CCTA should be considered to rule out CAD in patients with suspected CCS or biomarker-negative NSTEMI-ACS in case of low-to-intermediate clinical likelihood of CAD, or in patients unsuitable for non-invasive functional testing undergoing non-urgent, intermediate-, and high-risk NCS.	IIa
General risk-reduction strategies—Section 5	
Cardiovascular risk factors and lifestyle interventions	
Smoking cessation >4 weeks before NCS is recommended to reduce post-operative complications and mortality.	I
Control of CV risk factors—including blood pressure, dyslipidaemia, and diabetes—is recommended before NCS.	I
Pharmacological treatment	
For patients on diuretics to treat hypertension, transient discontinuation of diuretics on the day of NCS should be considered.	IIa
It should be considered to interrupt SGLT-2 inhibitor therapy for at least 3 days before intermediate- or high-risk NCS.	IIa
Antiplatelets	
For patients undergoing high bleeding risk surgery (e.g. intracranial, spinal neurosurgery, or vitreoretinal eye surgery), it is recommended to interrupt aspirin for at least 7 days pre-operatively.	I
In high-risk patients with a recent PCI (e.g. STEMI patients or high-risk NSTEMI-ACS patients), a DAPT duration of at least 3 months should be considered before time-sensitive NCS.	IIa
Anticoagulants	
When an urgent surgical intervention is required, it is recommended that NOAC therapy is immediately interrupted.	I
In non-minor bleeding risk procedures in patients using a NOAC, it is recommended to use an interruption regimen based on the NOAC compound, renal function, and bleeding risk.	I
In minor bleeding risk surgery and other procedures where bleeding can easily be controlled, it is recommended to perform surgery without interruption of OAC therapy.	I
In patients using NOACs, it is recommended that minor bleeding risk procedures are performed at trough levels (typically 12–24 h after last intake).	I
LMWH is recommended, as an alternative to UFH, for bridging in patients with MHVs and high surgical risk.	I
For patients with mechanical prosthetic heart valves undergoing NCS, bridging with UFH or LMWH should be considered if OAC interruption is needed and patients have: (i) mechanical AVR and any thromboembolic risk factor; (ii) old-generation mechanical AVR; or (iii) mechanical mitral or tricuspid valve replacement.	IIa
Idarucizumab should be considered in patients on dabigatran and requiring urgent surgical intervention with intermediate to high bleeding risk.	IIa
For interventions with a very high risk of bleeding, such as spinal or epidural anaesthesia, interruption of NOACs for up to five half-lives and re-initiation after 24 h should be considered.	IIa

Continued

When specific reversal agents are unavailable, PCC or activated PCC should be considered for reversing NOAC effects.	IIa
If an urgent surgical intervention is required, specific coagulation tests and assessment of NOAC plasma levels should be considered to interpret routine coagulation tests and waning of anticoagulant effect.	IIa
If bleeding risk with resumption of full-dose anticoagulation outweighs the risk of thromboembolic events, postponing therapeutic anticoagulation 48–72 h after the procedure may be considered, using post-operative thromboprophylaxis until resumption of full OAC dose is deemed safe.	IIb
Bridging of OAC therapy is not recommended in patients with low/moderate thrombotic risk undergoing NCS.	III
Use of reduced-dose NOAC to attenuate the risk of post-operative bleeding is not recommended.	III
Thromboprophylaxis	
It is recommended that decisions about peri-operative thromboprophylaxis in NCS are based on individual and procedure-specific risk factors.	I
If thromboprophylaxis is deemed necessary, it is recommended to choose the type and duration of thromboprophylaxis (LMWH, NOAC, or fondaparinux) according to type of NCS, duration of immobilization, and patient-related factors.	I
In patients with a low bleeding risk, peri-operative thromboprophylaxis should be considered for a duration of up to 14 or 35 days, for total knee or hip arthroplasty, respectively.	IIa
NOACs in thromboprophylaxis dose may be considered as alternative treatments to LMWH after total knee and hip arthroplasty.	IIb
Patient blood management	
It is recommended to measure haemoglobin pre-operatively in patients scheduled for intermediate- to high-risk NCS.	I
It is recommended to treat anaemia in advance of NCS in order to reduce the need for RBC transfusion during NCS.	I
In patients undergoing surgery with expected blood loss of ≥ 500 mL, use of washed cell salvage is recommended.	I
It is recommended to use point-of-care diagnostics for guidance of blood component therapy, when available.	I
The use of an algorithm to diagnose and treat anaemic patients before NCS should be considered.	IIa
In patients undergoing NCS and experiencing major bleeding, administration of tranexamic acid should be immediately considered.	IIa
Use of closed-loop arterial blood sampling systems should be considered to avoid blood loss.	IIa
Application of meticulous haemostasis should be considered a routine procedure.	IIa
A feedback/monitoring programme or clinical decision support system should be considered to be assessed before blood transfusion.	IIa
Before allogenic blood transfusion, it should be considered to obtain an extensive consent about risks associated with transfusion.	IIa

Continued

Specific diseases—Section 6	
Coronary artery disease	
Pre-operative evaluation of patients with an indication for PCI by an expert team (surgeon and cardiologist) should be considered before elective NCS.	IIa
Heart failure	
In patients with HF undergoing NCS, it is recommended to regularly assess volume status and signs of organ perfusion.	I
A multidisciplinary team including VAD specialists is recommended for peri-operative management of patients with HF receiving mechanical circulatory support.	I
Valvular heart disease	
In patients with symptomatic severe AR or asymptomatic severe AR and LVESD >50 mm or LVESDi (LVESD/BSA) >25 mm/m ² (in patients with small body size) or resting LVEF $\leq 50\%$, valve surgery is recommended prior to elective intermediate- or high-risk NCS.	I
In patients with moderate-to-severe rheumatic MS and symptoms or SPAP >50 mmHg, valve intervention (PMC or surgery) is recommended before elective intermediate- or high-risk NCS.	I
In asymptomatic patients with severe AS who are scheduled for elective high-risk NCS, AVR (SAVR or TAVI) should be considered after Heart Team discussion.	IIa
In patients with symptomatic severe primary MR or asymptomatic severe primary MR with LV dysfunction (LVESD ≥ 40 mm and/or LVEF $\leq 60\%$), valve intervention (surgical or transcatheter) should be considered prior to intermediate- or high-risk NCS, if time allows.	IIa
In patients with severe secondary MR who remain symptomatic despite guideline-directed medical therapy (including CRT if indicated), valve intervention (transcatheter or surgical) should be considered before NCS, in eligible patients with an acceptable procedural risk.	IIa
In patients with severe symptomatic AS in need of time-sensitive NCS or in whom the TAVI and SAVR are unfeasible, BAV may be considered before NCS as a bridge to definitive aortic valve repair.	IIb
Arrhythmias	
In AF patients with acute or worsening haemodynamic instability undergoing NCS, emergency electrical cardioversion is recommended.	I
In patients with symptomatic, monomorphic, sustained VT associated with myocardial scar, recurring despite optimal medical therapy, ablation of arrhythmia is recommended before elective NCS.	I
It is recommended that all patients with CIEDs that are reprogrammed before surgery have a re-check and necessary reprogramming as soon as possible after the procedure.	I
If indications for pacing exist according to the 2021 ESC Guidelines on cardiac pacing and cardiac resynchronization therapy, NCS surgery should be deferred and implantation of a permanent pacemaker should be considered.	IIa

Continued

Ablation should be considered in symptomatic patients with recurrent or persistent SVT, despite treatment, prior to high-risk, non-urgent NCS.	IIa
In high-risk CIED patients (e.g. with ICD or being pacing-dependant) undergoing NCS carrying a high probability of electromagnetic interference (e.g. involving unipolar electrosurgery above the umbilical area), CIED check-up and necessary reprogramming immediately before the procedure should be considered.	IIa
Adult congenital heart disease	
In patients with ACHD, a consultation with an ACHD specialist is recommended before intermediate- or high-risk surgery.	I
In patients with ACHD, it is recommended that intermediate- and high-risk elective surgery is performed in a centre with experience in the care of ACHD patients.	I
Pericardial diseases	
In patients with acute pericarditis, deferring elective NCS until complete resolution of the underlying process should be considered.	IIa
Avoiding elective NCS procedures under general anaesthesia until colchicine or the immunosuppressive treatment course for pericardial disease is completed may be considered.	IIb
Pulmonary arterial hypertension	
Inodilator drugs (dobutamine, milrinone, levosimendan), which increase cardiac output and lower pulmonary vascular resistance, should be considered peri-operatively according to the haemodynamic status of the patient.	IIa
Peripheral artery disease and/or abdominal aortic aneurysm	
Routine referral for cardiac work-up, coronary angiography, or CPET prior to elective surgery for PAD or AAA is not recommended.	III
Renal disease	
In patients with known risk factors (age >65 years, BMI >30, diabetes, hypertension, hyperlipidaemia, CV disease, or smoking) undergoing intermediate- or high-risk NCS, it is recommended to screen for pre-operative renal disease by measuring serum creatinine and GFR.	I
In patients with renal disease requiring peri-operative contrast-enhanced radiography, balanced hydration with i.v. isotonic fluids, the use of a minimal volume of contrast media, and the use of low-osmolar or iso-osmolar contrast media should be considered.	IIa
If a cystatin C measurement assay is available, cystatin C measurement should be considered in patients with impaired eGFR (<45–59 mL/min/1.73 m ²) to confirm kidney disease.	IIa
Obesity	
It is recommended to assess cardiorespiratory fitness to estimate peri-operative CV risk in obese patients, with particular attention to those undergoing intermediate- and high-risk NCS.	I
In patients at high risk of obesity hypoventilation syndrome, additional specialist investigation before major elective NCS should be considered.	IIa

Continued

Diabetes mellitus	
A pre-operative assessment for concomitant cardiac conditions is recommended in patients with diabetes with suspected or known CAD, and those with autonomic neuropathy, retinopathy, or renal disease and scheduled to undergo intermediate- or high-risk NCS.	I
Peri-operative monitoring and anaesthesia—Section 7	
It is recommended to avoid post-operative acute pain.	I
Perioperative cardiovascular complications—Section 8	
It is recommended to have high awareness of peri-operative CV complications combined with surveillance for PMI in patients undergoing intermediate- or high-risk NCS.	I
Systematic PMI work-up is recommended to identify the underlying pathophysiology and to define therapy.	I
It is recommended to treat post-operative STEMI, NSTEMI-ACS, acute HF, and tachyarrhythmias in accordance with guidelines for the non-surgical setting, after interdisciplinary discussion with the surgeon about bleeding risk.	I
In patients with post-operative PE of high or intermediate clinical probability, initiation of anticoagulation is recommended without delay, while diagnostic work-up is in progress, if bleeding risk is low.	I
Post-operative oral anticoagulation for PE is recommended to be administered for a period of at least 3 months.	I
In patients with a post-operative indication for OAC, NOACs are generally recommended over VKA.	I
In patients with post-operative AF after NCS, long-term OAC therapy should be considered in all patients at risk of stroke, considering the anticipated net clinical benefit of OAC therapy, and informed patient preferences.	IIa
In patients with MINS and at low risk of bleeding, treatment with dabigatran 110 mg orally <i>b.i.d.</i> may be considered from about 1 week after NCS.	IIb
Routine use of beta-blocker for the prevention of post-operative AF in patients undergoing NCS is not recommended.	III

AAA, abdominal aortic aneurysm; ACHD, adults with congenital heart disease; AF, atrial fibrillation; AR, aortic valve regurgitation; AS, aortic valve stenosis; AVR, aortic valve replacement; BAV, balloon aortic valvuloplasty; *b.i.d.*, twice a day; BMI, body mass index; BNP, B-type natriuretic peptide; BSA, body surface area; CABG, coronary artery bypass graft; CAD, coronary artery disease; CCS, chronic coronary syndrome; CCTA, coronary computed tomography angiography; CIED, cardiac implantable electronic device; CPET, cardiopulmonary exercise testing; CRT, cardiac resynchronization therapy; CV, cardiovascular; CVD, cardiovascular disease; DAPT, dual antiplatelet therapy; ECG, electrocardiogram; eGFR, estimated glomerular filtration rate; ESC, European Society of Cardiology; FOCUS, focused cardiac ultrasound; GFR, glomerular filtration rate; HF, heart failure; i.v., intravenous; LMWH, low molecular weight heparin; LV, left ventricular; LVEF, left ventricular ejection fraction; LVESD, left ventricular end-systolic diameter; LVESDI, left ventricular end-systolic dimension index; MHV, mechanical heart valve; MINS, myocardial injury following non-cardiac surgery; MR, mitral valve regurgitation; MS, mitral valve stenosis; NCS, non-cardiac surgery; NOAC, non-vitamin K antagonist oral anticoagulant; NSTEMI-ACS, non-ST-segment elevation acute coronary syndrome; NT-proBNP, N-terminal pro-B-type natriuretic peptide; OAC, oral anticoagulant; PAD, peripheral artery disease; PCC, prothrombin complex concentrate; PCI, percutaneous coronary intervention; PE, pulmonary embolism; PMC, percutaneous mitral commissurotomy; PMI, peri-operative myocardial infarction/injury; RBC, red blood cell; SAVR, surgical aortic valve replacement; SGLT-2, sodium-glucose co-transporter-2; SPAP, systolic pulmonary artery pressure; STEMI, ST-segment elevation myocardial infarction; SVT, supraventricular tachycardia; TAVI, transcatheter aortic valve implantation; TTE, transthoracic echocardiography; UFH, unfractionated heparin; VAD, ventricular assist device; VKA, vitamin K antagonist; VT, ventricular tachycardia.

Table 4B Revised recommendations

Recommendations in 2014 version	Class	Recommendations in 2022 version	Class
Preoperative assessment tools—Section 4			
Electrocardiography and biomarkers			
Pre-operative ECG is recommended for patients who have risk factor(s) and are scheduled for intermediate- or high-risk surgery.	I	In patients who have known CVD or CV risk factors (including age ≥ 65 years), or symptoms or signs suggestive of CVD it is recommended to obtain a pre-operative 12-lead ECG before intermediate- or high-risk NCS.	I
Assessment of cardiac troponins in high-risk patients, both before and 48–72 h after major surgery, may be considered.	IIb	In patients who have known CVD, CV risk factors (including age ≥ 65 years), or symptoms suggestive of CVD, it is recommended to measure hs-cTn T or hs-cTn I before intermediate- and high-risk NCS, and at 24 h and 48 h afterwards.	I
NT-proBNP and BNP measurements may be considered for obtaining independent prognostic information for peri-operative and late cardiac events in high-risk patients.	IIb	In patients who have known CVD, CV risk factors (including age ≥ 65 years), or symptoms suggestive of CVD, it should be considered to measure BNP or NT-proBNP before intermediate- and high-risk NCS.	IIa
Universal pre-operative routine biomarker sampling for risk stratification and to prevent cardiac events is not recommended.	III	In low-risk patients undergoing low- and intermediate-risk NCS, it is not recommended to routinely obtain pre-operative ECG, hs-cTn T/I, or BNP/NT-proBNP concentrations.	III
Coronary angiography			
Pre-operative ICA is not recommended in cardiac-stable patients undergoing low-risk surgery.	III	Routine pre-operative ICA is not recommended in stable CCS patients undergoing low- or intermediate-risk NCS.	III
General risk-reduction strategies—Section 5			
Pharmacological treatment			
Transient discontinuation of ACEIs or ARBs before NCS in hypertensive patients should be considered.	IIa	In patients without HF, withholding RAAS inhibitors on the day of NCS should be considered to prevent peri-operative hypotension.	IIa
Antiplatelets			
Consideration should be given to performing non-urgent NCS in patients who have had recent DES implantation no sooner than 12 months following the intervention. This delay may be reduced to 6 months for the new-generation DES.	IIa	It is recommended to delay elective NCS until 6 months after elective PCI and 12 months after an ACS.	I
It is recommended that aspirin be continued for 4 weeks after BMS implantation and for 3–12 months after DES implantation, unless the risk of life-threatening surgical bleeding on aspirin is unacceptably high.	I	After elective PCI, it is recommended to delay time-sensitive NCS until a minimum of 1 month of DAPT treatment has been given.	I
Continuation of aspirin, in patients previously thus treated, may be considered in the peri-operative period, and should be based on an individual decision that depends on the peri-operative bleeding risk, weighed against the risk of thrombotic complications.	IIb	In patients with a previous PCI, it is recommended to continue aspirin peri-operatively if the bleeding risk allows.	I
Discontinuation of aspirin therapy, in patients previously treated with it, should be considered in those in whom haemostasis is anticipated to be difficult to control during surgery.	IIa	In patients without a history of PCI, interruption of aspirin at least 3 days before NCS may be considered if the bleeding risk outweighs the ischaemic risk, to reduce the risk of bleeding.	IIb
In patients treated with P2Y ₁₂ inhibitors, who need to undergo surgery, postponing surgery for at least 5 days after cessation of ticagrelor and clopidogrel—and for 7 days in the case of prasugrel—if clinically feasible, should be considered unless the patient is at high risk of an ischaemic event.	IIa	If interruption of P2Y ₁₂ inhibitor is indicated, it is recommended to withhold ticagrelor for 3–5 days, clopidogrel for 5 days, and prasugrel for 7 days prior to NCS.	I
Specific diseases—Section 6			
Coronary artery disease			
If PCI is indicated before semi-urgent surgery, the use of new-generation DES, BMS or even balloon angioplasty is recommended.	I	If PCI is indicated before NCS, the use of new-generation DES is recommended over BMS and balloon angioplasty.	I

Continued

Arrhythmias			
Patients with ICDs, whose devices have been pre-operatively deactivated, should be on continuous cardiac monitor throughout the period of deactivation. External defibrillation equipment should be readily available.	I	It is recommended that patients with temporarily deactivated ICDs have continuous ECG monitoring, and during the peri-operative period are accompanied by personnel skilled in early detection and treatment of arrhythmias. In high-risk patients (e.g. pacemaker-dependant or ICD patients), or if access to the torso will be difficult during the procedure, it is recommended to place transcutaneous pacing/defibrillation pads prior to NCS.	I
Hypertension			
Large peri-operative fluctuations in blood pressure in hypertensive patients should be avoided.	IIa	In patients with chronic hypertension undergoing elective NCS, it is recommended to avoid large peri-operative fluctuations in blood pressure, particularly hypotension, during the peri-operative period.	I
Clinicians may consider not deferring NCS in patients with grade 1 or 2 hypertension (systolic blood pressure <180 mmHg; diastolic blood pressure <110 mmHg).	IIb	It is not recommended to defer NCS in patients with stage 1 or 2 hypertension.	III
Peripheral artery disease			
Patients with PAD should be clinically assessed for ischaemic heart disease and, if more than two clinical risk factors are present, they should be considered for pre-operative stress or imaging testing.	IIa	In patients with poor functional capacity or with significant risk factors or symptoms (such as moderate-to-severe angina pectoris, decompensated HF, valvular disease and significant arrhythmia), referral for cardiac work-up and optimization is recommended prior to elective surgery for PAD or AAA.	I
Diabetes mellitus			
In patients at high surgical risk, clinicians should consider screening for elevated HbA1c before major surgery and improving pre-operative glucose control.	IIa	In patients with diabetes or disturbed glucose metabolism, a pre-operative HbA1c test is recommended, if this measurement has not been performed in the previous 3 months. In case of HbA1c $\geq 8.5\%$ (≥ 69 mmol/mol), elective NCS should be postponed, if safe and practical.	I
Peri-operative monitoring and anaesthesia—Section 7			
Patients with high cardiac and surgical risk should be considered for goal-directed therapy.	IIa	In order to preserve optimal CV stability, it is recommended to apply goal-directed haemodynamic therapy in patients undergoing high-risk NCS.	I
Avoiding arterial hypotension (mean arterial pressure <60 mmHg) for prolonged cumulative periods (>30 min) may be considered.	IIb	In order to minimize the risk of post-operative organ dysfunction, it is recommended to avoid an intra-operative mean arterial pressure decrease of >20% from baseline values or <60–70 mmHg for ≥ 10 min.	I
Avoiding non-steroidal anti-inflammatory drugs (especially cyclo-oxygenase-2 inhibitors) as the first-line analgesics in patients with IHD or stroke may be considered.	IIb	Non-aspirin NSAIDs are not recommended as first-line analgesics in patients with established or high risk of CVD.	III

AAA, abdominal aortic aneurysm; ACEI, angiotensin-converting-enzyme inhibitor; ARB, angiotensin receptor blocker; BNP, B-type natriuretic peptide; BMS, bare metal stent; CCS, chronic coronary syndrome; CV, cardiovascular; CVD, cardiovascular disease; DAPT, dual antiplatelet therapy; DES, drug-eluting stent; ECG, electrocardiogram; HbA1c, glycated haemoglobin A1c; HF, heart failure; hs-cTn, high-sensitivity cardiac troponin; ICA, invasive coronary angiography; ICD, implantable cardioverter-defibrillator; IHD, ischaemic heart disease; NCS, non-cardiac surgery; NSAID, non-steroidal anti-inflammatory drug; NT-proBNP, N-terminal pro-B-type natriuretic peptide; PAD, peripheral artery disease; PCI, percutaneous coronary intervention; RAAS, renin-angiotensin-aldosterone system.

2.2. The magnitude of the problem

The annual volume of major surgery worldwide is estimated to be more than 300 million patients (about 5% of the world population), which is a 34% increase from 2004 to 2012.^{1,2} Nearly 74% of these operations are performed in countries spending substantial amounts on health care. When applied to European Union countries, which

had an overall population of 448 million in 2020 (27 countries), this figure translates into a crude estimate of nearly 22 million major procedures annually.²

Nearly 85% of major operations are non-cardiac surgical procedures.³ In a recent report from the USA National Inpatient Sample database, nearly half of adults aged ≥ 45 years undergoing major non-

cardiac surgery (NCS) presented with at least two cardiovascular (CV) risk factors, 18% had coronary artery disease (CAD), 4.7% had a history of stroke, and 7.7% had a modified Revised Cardiac Risk Index (RCRI) score ≥ 3 (range 0–6) in 2012–13. These prevalence rates show a substantial increase compared with the equivalent rates in 2008–09.⁴ In a large registry including 37 915 consecutive patients undergoing percutaneous coronary interventions (PCIs) with drug-eluting stent (DES), the rates of NCS after PCI were 11% and 24%, 1 and 3 years after PCI respectively. The cut-off ages at which NCS was more likely to occur within 1 and 3 years of PCI were 62 and 73 years respectively.⁵

The prevalence of comorbidities, the clinical condition of patients before surgery, and the urgency, magnitude, type, and duration of the surgical procedure determine the risk of peri-operative complications. In a recent cohort study of 40 000 patients aged ≥ 45 years undergoing inpatient NCS, one of seven experienced a major cardiac or cerebrovascular complication at 30 days.⁶ Cardiovascular complications can particularly occur in patients with documented or asymptomatic coronary heart disease, left ventricular (LV) dysfunction, valvular heart disease (VHD), and arrhythmias, who undergo surgical procedures that are associated with prolonged haemodynamic and cardiac stress. In the case of peri-operative myocardial ischaemia, three mechanisms are important: (i) oxygen supply–demand mismatch on the background of coronary artery stenosis that may become flow-limiting by peri-operative haemodynamic fluctuations; (ii) acute coronary syndrome (ACS) due to stress-induced erosion or rupture of a vulnerable atherosclerotic plaque in combination with pro-inflammatory and hypercoagulable states induced by surgery, and the haemodynamic distress resulting from fluid shifts and anaesthesia; and (iii) surgery-associated bleeding risk requiring interruption of antiplatelet therapies, which might lead to stent thrombosis among patients undergoing NCS after recent coronary stent placement. Left ventricular dysfunction and arrhythmias may occur for various reasons at all ages. Because the prevalence of CAD, VHD, heart failure, and arrhythmias increases with age, peri-operative CV mortality and morbidity are predominantly an issue in the adult population undergoing major NCS.

In Europe, recent systematic data on the annual number and type of operations, and on patient outcomes are unfortunately lacking. Additionally, data definitions vary, as do data quantity and quality. Based on the estimates outlined above, nearly 6.6 million procedures are performed annually in European patients with CAD, peripheral artery disease (PAD), and cerebrovascular disease who are at high risk of CV complications. In a 7 day cohort study, the European Surgical Outcomes Study (EuSOS) group investigated the outcomes of NCS in 498 hospitals across 27 European nations and the UK; up to 8% of patients undergoing NCS required critical care admission, while in-hospital mortality ranged 1.4–21.5% (mean 4.0%), depending on safety precautions.⁷ In a recent prospective study of 2265 high-risk patients undergoing NCS in Switzerland, one out of five developed major adverse events within 365 days.⁸ When applied to the population in European Union countries, these figures translate into at least 660 000 major cardiac or cerebrovascular complications occurring annually due to NCS procedures.

The 2022 ESC Guidelines on cardiovascular assessment and management of patients undergoing NCS focus on the pre-operative CV risk assessment and peri-operative management of patients in whom

cardiovascular disease (CVD) is a potential source of complications during NCS.

2.3. Change in demographics

Within the next 30 years, the ageing of the population will have a major impact on peri-operative patient management. Patients undergoing NCS are older than the rest of the population. Furthermore, it is estimated that by 2030, one-fifth of individuals aged >75 years will undergo surgery each year. In addition, between 2018 and 2050, the number of people in Europe aged 75–84 years is projected to increase by $\sim 60\%$. The total number of surgical procedures may increase even faster because of the greater need for interventions with increasing age. Demographics of patients undergoing surgery show trends towards increasing numbers of elderly patients and increasing numbers of patients with comorbidities, particularly CVDs. Thus, adults aged ≥ 75 years have a greater risk of peri-operative major adverse cardiovascular events (MACEs) (9.5% vs. 4.8% for younger adults [$P < 0.001$]).⁹ However, age per se seems to be responsible for a small increase in the risk of complications; greater risks are associated with urgency and significant CV, pulmonary, and renal disease.

2.4. Purpose

As many years have passed and new evidence has become available since the publication of the 2014 ESC/European Society of Anaesthesiology (ESA) Guidelines on non-cardiac surgery: cardiovascular assessment and management,¹⁰ the ESC has decided to revise the guidelines on NCS. These new guidelines are based on the 2014 edition, but all sections have been revised or rewritten, and several new sections have been added. Some of the old recommendations are unchanged or have been revised, and new recommendations have been added.

These guidelines are intended for physicians, healthcare workers, and collaborators involved in the pre-operative, operative, and post-operative care of patients undergoing NCS. The objective is to endorse a standardized and evidence-based approach to peri-operative CV management. The guidelines recommend a stepwise evaluation of the patient that integrates clinical risk factors and test results with the estimated stress of the planned surgical procedure and the risks involved with the discontinuation of drugs. This results in an individualized risk assessment, with the opportunity of initiating medical therapy, coronary interventions, and specific surgical and anaesthetic techniques, or withholding medical therapy, in order to optimize the patient's peri-operative condition. Further, it should be discussed in which institutions (specialized small hospital vs. tertiary care) the NCS will be performed. It is important that patients' values and preferences with respect to the benefits and risks of surgery are taken into consideration, and that patients are involved in the decisions. This is particularly important when it comes to decisions about undergoing elective surgery or not, the timing of surgery, and choice of surgical and anaesthetic techniques.

Compared with non-surgical settings, randomized controlled trials (RCTs) are scarce in this field. However, since the publication of the 2014 ESC/ESA Guidelines on non-cardiac surgery: cardiovascular assessment and management there has been a significant increase in RCTs that are relevant in this setting. When no trials are available on a specific CV management regimen in the surgical setting, data from the non-surgical setting may be extrapolated and similar recommendations made, but with different levels of evidence.

These guidelines have the potential to improve peri- and post-operative outcomes and highlight the existence of a clear opportunity for improving the quality of care. Following the publication of these updated guidelines on NCS, their effects on outcomes should be monitored. The objective evaluations of the quality of the assessments and the outcomes are described in quality indicators (Section 13).

2.5. The outcomes we want to prevent

The recommendations in these guidelines are intended to prevent peri-operative CV morbidity and mortality, for example: peri-operative myocardial infarction/injury (PMI), stent thrombosis, acute heart failure (HF), haemodynamically relevant arrhythmias, pulmonary embolism (PE), ischaemic stroke, and death. It is also important to prevent bleeding complications, especially associated with antithrombotic treatment, since bleeding is associated with an increased risk of MI and death.^{6,11–13}

3. Clinical risk evaluation

Cardiovascular morbidity and mortality in patients undergoing NCS are determined by two main factors: patient-related risk and type of surgery or procedure, including the circumstances under which it

takes place (experience of institution, elective vs. emergency procedure).¹⁴ The risk may be reduced by an adequate pre-operative evaluation and proper selection of type and timing of the surgical procedure (Figure 1).

3.1. Surgery-related risk

The surgery-related risk is determined by the type and duration of the surgery, and the urgency of the procedure or intervention. The type of anaesthesia and anaesthetic drugs may also influence the risk of complications in patients at intermediate to high cardiac risk undergoing NCS (see Section 7).¹⁵ The surgical risk estimate is a broad approximation of 30 day risk of CV death, MI, and stroke, which only takes into account the specific surgical intervention without considering the patient’s comorbidities (Table 5).^{10,16}

Any surgical procedure may increase the level of cortisol and catecholamines as stress responses due to tissue injury and inflammation, and neuro–endocrine and sympathovagal imbalance. Changes in body core temperature, blood loss, and fluid shifts may cause a rise in vascular resistance as well as hypotension,¹⁷ leading to imbalance between myocardial oxygen demand and delivery. Bleeding, transfusion of blood products, tissue injury, and inflammatory response may affect the coagulation system, inducing a prothrombotic state.

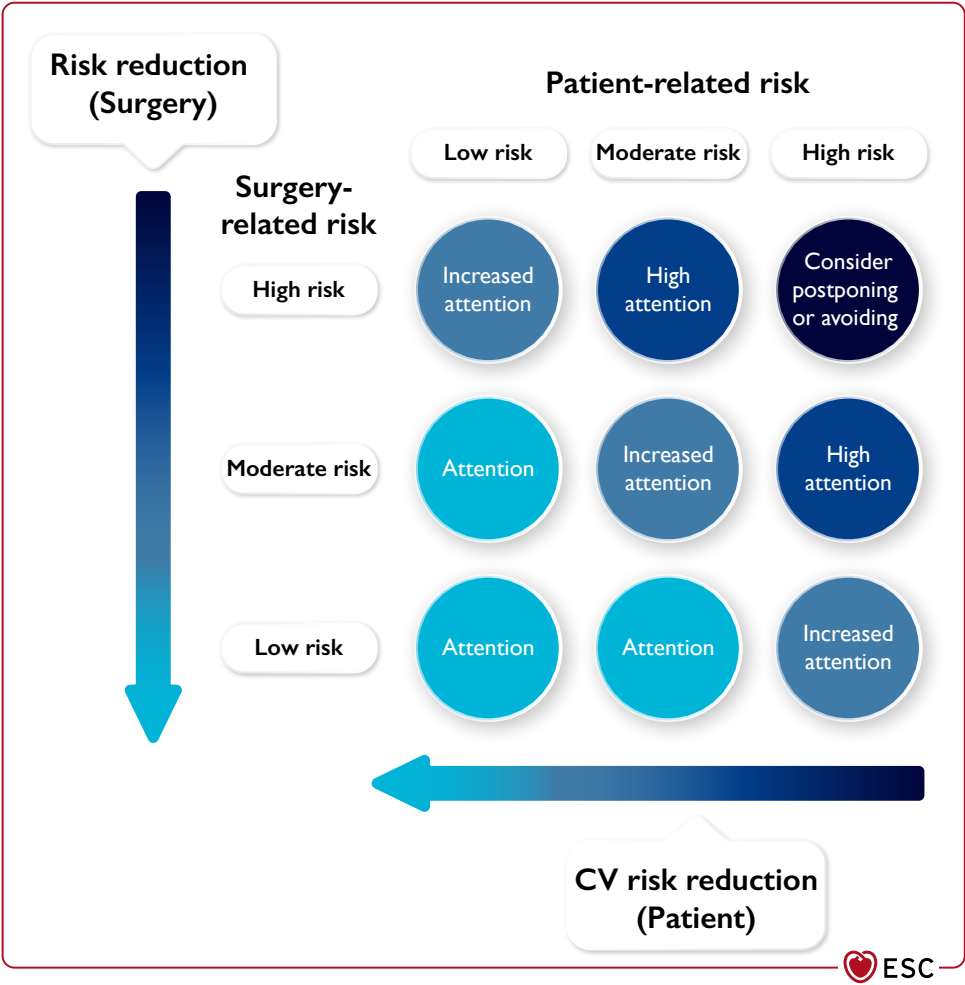

Figure 1 Total risk is an interaction of patient-related and surgery-related risk. Ideally, the total risk should be as close as possible to the lower left corner, by choosing surgery/procedure/anaesthesia/institution with the lowest possible risk along with efforts to mitigate the patient’s CV risk.

Table 5 Surgical risk estimate according to type of surgery or intervention

Low surgical risk (<1%)	Intermediate surgical risk (1–5%)	High surgical risk (>5%)
<ul style="list-style-type: none"> Breast Dental Endocrine: thyroid Eye Gynaecological: minor Orthopaedic minor (meniscectomy) Reconstructive Superficial surgery Urological minor: (transurethral resection of the prostate) VATS minor lung resection 	<ul style="list-style-type: none"> Carotid asymptomatic (CEA or CAS) Carotid symptomatic (CEA) Endovascular aortic aneurysm repair Head or neck surgery Intraperitoneal: splenectomy, hiatal hernia repair, cholecystectomy Intrathoracic: non-major Neurological or orthopaedic: major (hip and spine surgery) Peripheral arterial angioplasty Renal transplants Urological or gynaecological: major 	<ul style="list-style-type: none"> Adrenal resection Aortic and major vascular surgery Carotid symptomatic (CAS) Duodenal-pancreatic surgery Liver resection, bile duct surgery Oesophagectomy Open lower limb revascularization for acute limb ischaemia or amputation Pneumonectomy (VATS or open surgery) Pulmonary or liver transplant Repair of perforated bowel Total cystectomy

CAS, carotid artery stenting; CEA, carotid endarterectomy; CV, cardiovascular; MI, myocardial infarction; VATS, video-assisted thoracic surgery.

Surgical risk estimate is a broad approximation of 30 day risk of CV death, MI, and stroke that takes into account only the specific surgical intervention, without considering the patient's comorbidities.

© ESC 2022

3.1.1. Timing of surgery

In general, acute procedures carry a higher risk of complications than elective procedures. Uniform timing definitions are unfeasible, as the time spans may vary between diseases. These guidelines use the timing definitions below.

Immediate: surgery/intervention should be performed without any delay to save life or organ function.

Urgent: surgery/intervention should be performed without unnecessary delay to save life, limb, or organ function.

Time-sensitive: surgery/intervention should be performed as soon as possible as there is a time-dependent risk of losing limb or organ function, or increased risk of complications. Cancer surgery is typically time-sensitive, as is carotid surgery to prevent stroke in a symptomatic case. The time window for time-sensitive surgery will vary depending on the underlying disease.

Elective: surgery/intervention can be performed electively (not further defined) without significant risk of losing limb, or organ function, or increased risks of complications.

Many factors affect outcomes when comparing acute or time-sensitive vs. elective surgery: the general condition of the patient vs. the stage of the acute illness, and how far it has progressed. The best interests of the patient should be considered before deciding on treatment, informed consent to management should be obtained, if at all possible, and decisions should be clearly recorded.²⁴

The degree of urgency should also be considered (i.e. does the procedure need to be performed outside working hours or can it wait until the next day?). In general, competences and supportive functions are not always present in the evenings or during the night; thus, an overall evaluation of what best serves the patient is necessary. The optimal timing of NCS should be discussed within the multidisciplinary team, including

an anaesthesiologist, in order to achieve optimized anaesthesia for each patient (see [Section 7](#)).

3.2. Type of surgical approach

New surgical techniques have been introduced to replace open surgery and to reduce the overall risk for the patient.

3.2.1. Laparoscopy

Laparoscopic procedures, compared with open surgical procedures, have the advantage of causing less tissue trauma and intestinal paralysis, resulting in less incisional pain, better post-operative pulmonary function, significantly fewer wall complications, and diminished post-operative fluid shifts related to bowel paralysis.²⁵ However, the pneumoperitoneum required for these procedures results in elevated intra-abdominal pressure and a reduction in venous return. Typical physiological sequelae are secondary to increased intra-abdominal pressure and absorption of the gaseous medium used for insufflation.

While healthy individuals on controlled ventilation typically tolerate pneumoperitoneum, patients with CVD, some types of adults with congenital heart disease (ACHD), and obese patients may experience adverse consequences.²⁶ Pneumoperitoneum and Trendelenburg position result in increased mean arterial pressure, central venous pressure, mean pulmonary artery pressure, pulmonary capillary wedge pressure, and systemic vascular resistance impairing cardiac function.^{27,28} Therefore, compared with open surgery, the CV risk in patients with CVD is not necessarily reduced in patients undergoing laparoscopy, and both should be evaluated in the same way. This is especially true in patients undergoing interventions for morbid obesity, but also in other types of surgery, considering the risk of conversion to an open procedure.^{29,30} Superior short-term outcomes of laparoscopic vs. open procedures have been reported, depending on type of surgery, operator experience,

and hospital volume; however, few studies provide direct measures of cardiac complications.^{31–33} The benefit of laparoscopic procedures is probably greater in elderly patients, with reduced length of hospital stay, intra-operative blood loss, incidence of post-operative pneumonia, time to return of normal bowel function, incidence of post-operative cardiac complications, and wound infections.³⁴

3.2.1.1. Vascular and endovascular procedures

Endovascular abdominal aortic aneurysm repair (EVAR) is a procedure using femoral artery access only, and is therefore associated with lower operative mortality and morbidity than open repair. It minimizes the surgical risk in simultaneous surgery for the treatment of abdominal aortic aneurysm (AAA) and a non-cardiac disorder, and shortens the time delay from the treatment of AAA and the non-cardiac disorder in patients undergoing two-phase surgery.^{35–37} The early gain in mortality from EVAR procedures is lost after 3–4 years, compared with open surgical treatment, due to general morbidity (especially CV mortality) of AAA patients.

Various vascular and non-vascular NCS procedures bear different operative risks. While aortic and infra-inguinal vascular surgical procedures are both regarded as high-risk procedures, their risk can be modified by adequate peri-operative measures.³⁸ For patients undergoing treatment of femoropopliteal artery disease, an endovascular-first approach may be advisable in case of additional significant comorbidity. A meta-analysis of studies comparing open surgery with PCI for the treatment of femoropopliteal arterial disease showed that femoral bypass surgery was associated with higher morbidity (odds ratio [OR] 2.93; 95% confidence interval [CI], 1.34–6.41) but similar mortality at 30 days compared with endovascular treatment.³⁹

3.2.1.2. Video-assisted non-cardiac surgery

Video-assisted thoracic surgery (VATS) is supported by a trial showing fewer peri-operative complications and a better quality of life in the first year following surgery for stage 1 lung cancer compared with anterolateral thoracotomy.²⁰ Also, a large propensity matched study conducted by the European Society of Thoracic Surgeons (ESTS) showed fewer post-operative complications following VATS compared with open thoracotomy.²¹ Overall, the benefits seem greatest in patients with reduced functional lung capacity.

^bLevel of evidence.

3.3. Patient-related risk

3.3.1. Initial assessment

Patient-related risk is determined by patient’s age, the presence or absence of CV risk factors (e.g. smoking, hypertension, diabetes, dyslipidaemia, family disposition)⁴⁰ or established CV disease, and comorbidities.⁴¹

Identification of patients at risk of CV complications is of paramount importance to choice of therapy when non-surgical options are available, or when the type of surgery or anaesthesia impacts the risk of complications. When emergency surgery is needed, the evaluation must necessarily be limited; however, most clinical circumstances allow a systematic approach.

As an initial assessment, it is recommended that all patients scheduled for NCS are evaluated by accurate history and physical examination, with special emphasis on CV risk factors, established CV disease, and comorbidities.⁴⁰ It is also recommended to measure standard laboratory tests (e.g. haemoglobin and renal function) in all patients undergoing intermediate- to high-risk surgery. Based on this information, further assessment of patient-related risk can proceed depending on the surgery-related risk, as shown in [Figure 2](#). It is recommended to perform an electrocardiogram (ECG), assess the functional capacity, and/or measure biomarkers (cardiac troponins and/or N-terminal pro-B-type natriuretic peptide [NT-proBNP]/B-type natriuretic peptide [BNP]) depending on the patient-related and surgery-related risk ([Figure 2](#)). Detailed information on available tools for risk assessment, their prognostic ability, and indications to perform them is given in [Section 4](#). More details on pre-operative management of patients with specific CV diseases are given in [Section 6](#).

3.3.1.1. Patients aged <65 years without a history of cardiovascular disease or cardiovascular risk factors

Patients aged <65 years without signs, symptoms, or history of CVD or CV risk factors are considered to be of low risk, and can proceed to low- and moderate-risk surgery without additional pre-operative risk assessment.⁴¹ Before high-risk surgery, ECG and biomarkers should be considered (see [Sections 4.3](#) and [4.4](#)).⁴²

Patients without signs or symptoms of CVD, but with a family history of genetic cardiomyopathy (i.e. dilated, hypertrophic, arrhythmic, or restrictive cardiomyopathy, or LV non-compaction) should be evaluated with an ECG and an echocardiographic examination to rule out the presence of the disease, irrespective of the age.⁴³ No specific data are available in the literature regarding risk of family members without the phenotype; however, they are at risk of developing the disease, which may be subclinical at the time of the NCS.⁴³

3.3.1.2. Patients aged ≥65 years or with cardiovascular risk factors

Patients who are aged ≥65 years and patients with risk factors for CVD—such as hypertension, dyslipidaemia, or smoking—have an increased risk of having undetected CVD. The SCORE2 risk-prediction tool can be used to estimate their 10 year CVD risk outside the setting of NCS.⁴⁰ Patients who are aged ≥65 years and patients with risk factors for CVD also have an increased risk of peri-operative complications during NCS.^{41,44} These patients need additional assessment before intermediate- and high-risk surgery ([Figure 2](#)) and optimal treatment of risk factors.

© ESC 2022

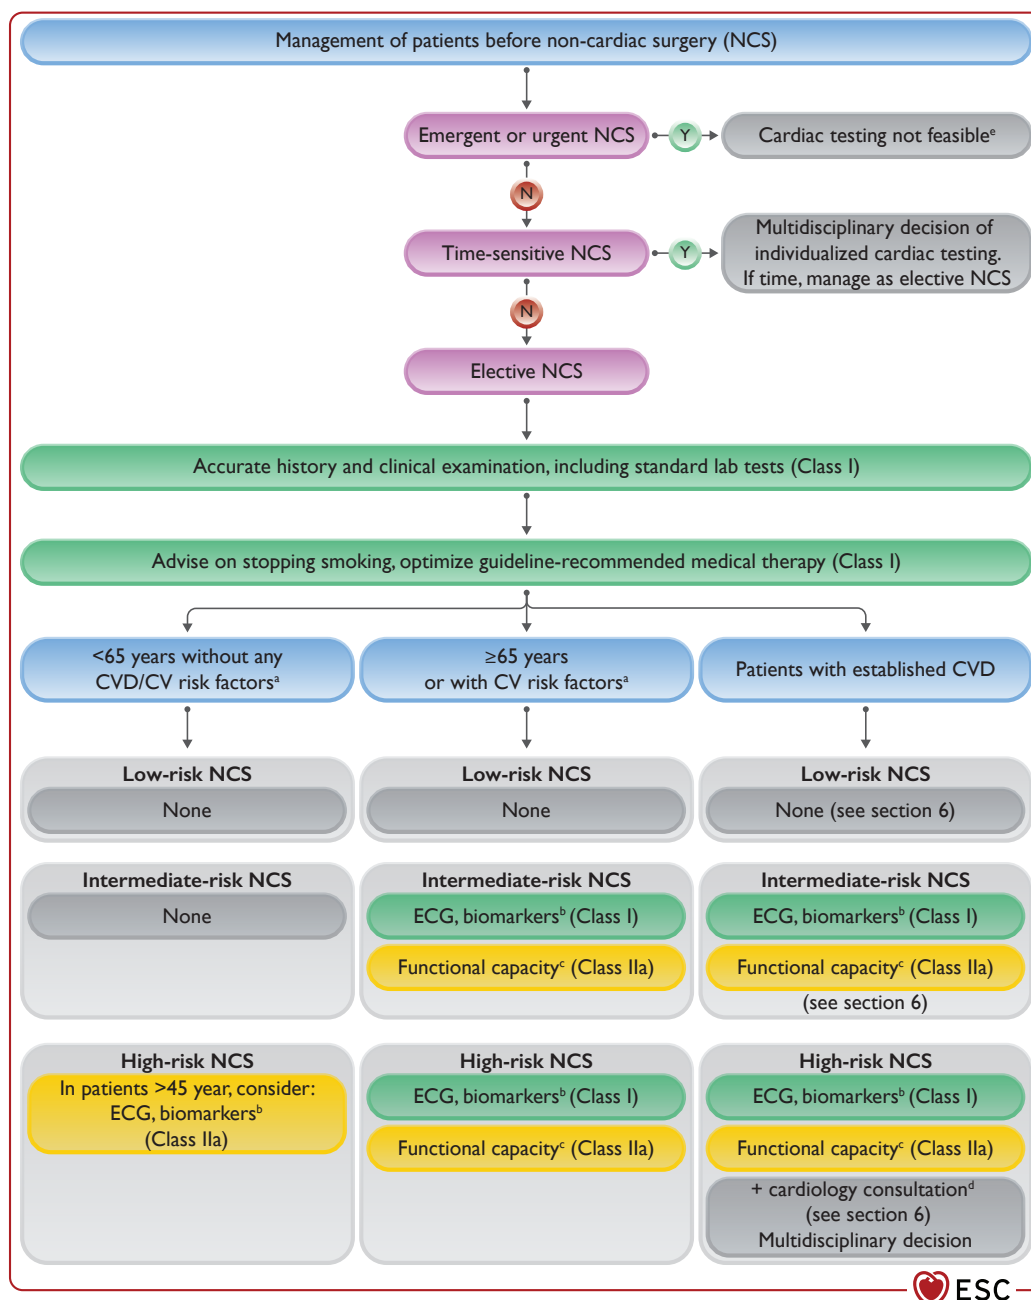

Figure 2 Pre-operative assessment before non-cardiac surgery. CV, cardiovascular; CVD, cardiovascular disease; ECG, electrocardiogram; N, no; NCS, non-cardiac surgery. Y, yes; ^aCV risk factors: hypertension, smoking, dyslipidaemia, diabetes, family history of CVD. ^bBiomarkers: hs-cTn T/I (Class I) and/or BNP/NT-proBNP (Class IIa). If pathological, consult a cardiologist. ^cFunctional capacity based on Duke Activity Status Index (DASI) or the ability to climb two flights of stairs. ^dFor diagnostic and therapeutic efforts to be considered, see [Section 6](#). ^eClose follow-up after intervention and subsequent management of heart disease are advised.

This is also the case for patients with other diseases known to be associated with a high risk of concomitant undetected or known CVD ([Sections 6.8 and 6.11–6.14](#)).

3.3.1.3. Patients with established cardiovascular disease

The surgical procedure has the potential to aggravate the disease and increase morbidity and mortality in patients with established

CVD. This may be preventable by implementing appropriate CV risk stratification prior to NCS and individually tailoring peri-operative therapy to reduce the risk.⁴⁵ If time allows, it is also recommended to optimize guideline-recommended treatment of the disease before NCS. See [Section 6](#) for a detailed discussion of risk assessment and management of patients with known CVD.

Recommendation Table 2 — Recommendations for all patients scheduled for non-cardiac surgery

Recommendations	Class ^a	Level ^b
In all patients scheduled for NCS, an accurate history and clinical examination are recommended.	I	C
It is recommended to perform a pre-operative risk assessment, ideally at the same time as the NCS is proposed. ^{46–53}	I	B
If time allows, it is recommended to optimize guideline-recommended treatment of CVD and CV risk factors before NCS.	I	C

CV, cardiovascular; CVD, cardiovascular disease; NCS, non-cardiac surgery.

Recommendations	Class ^a	Level ^b
In patients with a family history of genetic cardiomyopathy, it is recommended to perform an ECG and TTE before NCS, regardless of age and symptoms.	I	C
In patients aged 45–65 years without signs, symptoms, or history of CVD, ECG and biomarkers should be considered before high-risk NCS.	IIa	C

ECG, electrocardiogram; NCS, non-cardiac surgery; TTE, transthoracic echocardiography.

^aClass of recommendation.^bLevel of evidence.

3.3.2. Patients with murmurs, chest pain, dyspnoea, or peripheral oedema

Patients without known CVD and scheduled for elective or acute NCS are often referred to a cardiologist because of symptoms or signs that may be caused by CVD. Murmurs, chest pain, dyspnoea, and oedema may suggest severe CVD, but may also be caused by non-cardiac disease. Thus, the medical history, family history, and risk factors have to be obtained and considered. The patient's physical capacity should be assessed. The need for further evaluation of the patient should be decided according to the risk of the planned procedure or surgery.

3.3.2.1. Murmurs

In a patient with a heart murmur, but without any symptoms of CVD, the value of performing an echocardiogram is not well-established and consensus is missing.^{54–56} However, if a heart murmur suggesting clinically significant pathology is present before high-risk NCS, it is recommended to perform an echocardiogram, even in patients without any symptoms of CVD. Old age or increased NT-proBNP may

increase the pre-test probability of haemodynamically significant but asymptomatic valvular disease. If the patient with the murmur also has symptoms of CVD, an echocardiogram is indicated before all NCS. The pre-operative setting is challenging, as the need for NCS and the risk of CVD have to be considered as independent factors. Thus, an echocardiogram may be useful in risk stratification for some patients, but whether it would improve outcome is uncertain. It is important to bear in mind that the time delay when performing additional but unnecessary examinations may worsen the patient's prognosis.⁵⁷ It has also been discussed that a focused cardiac ultrasound (FOCUS) could replace auscultation in general in the pre-operative evaluation of patients.⁵⁸ While cardiac auscultation has severe limitations,^{59,60} the value of performing a FOCUS as a standard pre-operative evaluation remains uncertain. Cardiac auscultation should not be replaced by FOCUS.

3.3.2.2. Chest pain

Patients scheduled for NCS may also present with previously unrecognized symptoms suggestive of CAD. The disease leading to the need for NCS may aggravate a subclinical CAD, or the patient may have a concomitant undetected CAD. In an elective setting, if the symptoms are suggestive of CAD, the guidelines for CAD patients in the non-surgical setting should be followed (see [Sections 4.5.3 and 6.1.2](#)). If immediate, urgent, or time-sensitive NCS is needed, the time for and access to adequate diagnostic tools may be limited. However, ECG and troponins can be used to detect or exclude ACS (see [Sections 4.3 and 4.4](#)).

3.3.2.3. Dyspnoea

Dyspnoea is a symptom of a wide range of diseases and conditions. In a large series of patients, self-reported dyspnoea identified a subgroup of otherwise asymptomatic patients at increased risk of death from CVD and any cause.⁶¹ In the diagnostic work-up to find the reason for dyspnoea, spirometry, D-dimer, NT-proBNP/BNP, arterial blood gases, and transthoracic echocardiography (TTE) have diagnostic utility⁶¹ but limited specificity. If NT-proBNP/BNP is elevated, an echocardiogram should be performed. If NT-proBNP/BNP is not elevated, other reasons for dyspnoea should be explored.

3.3.2.4. Peripheral oedema

Increased hydrostatic pressure leading to oedema is a feature of a wide range of CV diseases, but an upright position is also a common cause of oedema. There is a spectrum of other diseases that can result in peripheral oedema not listed here.

Recommendation Table 4 — Recommendations for pre-operative assessment in patients with previously unknown murmur, angina, dyspnoea, or peripheral oedema

Recommendations	Class ^a	Level ^b
Newly detected murmur		
In patients with a newly detected murmur and symptoms or signs of CVD, TTE is recommended before NCS.	I	C

Continued

In patients with a newly detected murmur suggesting clinically significant pathology, TTE is recommended before high-risk NCS.	I	C
In patients with a newly detected murmur, but without other signs or symptoms of CVD, TTE should be considered before moderate-risk NCS.	IIa	C
Previously unknown angina		
If a patient scheduled for elective NCS has chest pain or other symptoms suggestive of undetected CAD, further diagnostic work-up before NCS is recommended.	I	C
If a patient in need of acute NCS also has chest pain or other symptoms suggestive of undetected CAD, a multidisciplinary assessment approach is recommended to choose the treatment with lowest total risk for the patient.	I	C
Dyspnoea and/or peripheral oedema		
In patients with dyspnoea and/or peripheral oedema, an ECG and an NT-proBNP/BNP test is indicated before NCS, unless there is a certain non-cardiac explanation.	I	C
In patients with dyspnoea and/or peripheral oedema and elevated NT-proBNP/BNP, TTE is recommended before NCS. ^c	I	C

BNP, B-type natriuretic peptide; CAD, coronary artery disease; CVD, cardiovascular disease; ECG, electrocardiogram; NCS, non-cardiac surgery; NT-proBNP, N-terminal pro-B-type natriuretic peptide; TTE, transthoracic echocardiography.

^aClass of recommendation.

^bLevel of evidence.

^cIf BNP/NT-proBNP testing is unavailable, TTE should be considered.

3.4. Timing of adequate risk evaluation

Pre-operative CV assessment should be performed prior to surgery, ideally at the time when the decision for NCS has been made. Accurate estimates of the risks and benefits of surgery is a prerequisite for informed decision-making by both physicians and patients about the appropriateness of surgery. These estimates should also help in guiding surgical (endovascular/endoscopic vs. open approach) and monitoring (intermediate care, screening for CV complications) approaches, and help to detect an unexpectedly high CV risk.⁴⁷ Therefore, the prognostic value of pre-operative CV risk assessment is much higher in elective vs. immediate or urgent surgery. Explicit communication of peri-operative CV risk, on the basis of the expected event rates,⁴⁷ and risk communication tools such as the A to Z Inventory of Decision Aids (<https://decisionaid.ohri.ca/AZinvent.php>) are recommended.

3.5. Avoidance or allowance for surgery in the individual patient

In the clinical setting it can be difficult to decide whether CVD represents a contraindication to NCS. In general, the risk for the patient if not operated on must be considerably higher than the risk of the treatment. Ideally, an unstable cardiac patient should be stabilized before NCS, but waiting can be detrimental for acute surgical disease. No definite list can be made for which cardiac disease is a clear contraindication to NCS, but in patients with severe HF (New York Heart

Association [NYHA] class IV), cardiogenic shock, severe pulmonary hypertension, or patients with severe frailty (see [Section 4.1.2](#) for frailty assessment), high-risk NCS should probably be avoided. Life expectancy and quality of life should also be taken into consideration. However, the decision should be made after discussions between the surgeon, anaesthesiologist, cardiologist, and also a geriatrician for elderly patients, along with the patient and relatives.

3.6. The patient perspective

Patients with established CVD may face concerns about their underlying disease and current CV medication, co-ordination between the surgical team and their cardiologist (examples provided in [Figure 3](#)), and the potential excessive risk compared with the expected outcome of the surgery. Time should be allowed to address concerns and to provide evidence-based information on the risk–benefit trade-offs and the surgical treatment options (including non-surgical or ‘do nothing’ alternatives) to ensure informed consent, and to allow patients to engage in shared decision-making with the aim of supporting the best decision. The team needs to understand the patient’s concerns and expectations about the treatment and short- and long-term goals, as the risk-benefits of the intervention may not be aligned with patient preferences and wishes. Communicating in plain language (oral and written) and targeting communication to fit the individual level of health literacy is pivotal. Several studies have indicated a relatively high prevalence of limited health literacy in patients with CVD (e.g. with HF)⁶² and limited health literacy is associated with adverse outcomes.⁶³ An example of a patient information sheet to be used in the communication with patients is given in the [Supplementary data, Table S1](#).

Recent systematic reviews and meta-analyses have focused on shared decision-making in the field of surgery across disease areas.^{64–67} In general, shared decision-making positively impacts decisional conflicts, knowledge gained, satisfaction, and decisional anxiety (although cultural variations may exist).⁶⁷ In the breast cancer/endocrine and urology specialties, decision-making and communication aids appear to be effective methods for supporting patients’ involvement in decision-making when undergoing elective surgery. Moreover, educational information, provided through interactive multimedia, computer, or on DVD, used prior to the surgical consultation could enhance the decision-making process in addition to face-to-face communication.⁶⁶

In Europe, the prevalence of pre-operative anxiety among patients undergoing surgical procedures varies from 27–80%.⁶⁸ Although a certain level of anxiety in patients must be expected, peri-operative anxiety is associated with worse surgical outcomes and longer recovery,^{69–72} which highlights the importance of pre-surgical assessment and, in some patients, treatment of anxiety. Factors associated with pre-operative anxiety are complex and include, among others, age, sex, educational level, type of surgery, and fear of post-operative complications or the outcome.⁶⁸ Psychological reactions in patients undergoing high- or medium-high-risk procedures and/or patients with previous negative experiences of NCS may warrant particular attention. Concerns and fears expressed by patients and relatives should be taken seriously. A number of reviews and meta-analyses have summarized the effects of interventions on surgical outcomes in abdominal, cardiac, and orthopaedic surgery, which may also be applicable to patients with CV conditions in these settings.^{73–75}

Recommendation Table 5 — Recommendations for patient information

Recommendations	Class ^a	Level ^b
It is recommended to give patients individualized instructions for pre-operative and post-operative changes in medication, in verbal and written formats with clear and concise directions.	I	C
It should be considered to set up a structured information list (e.g. a check list to help with common issues) for patients with CVD or at high risk of CV complications scheduled for NCS.	Ila	C

4. Pre-operative assessment tools

4.1. Risk scores

4.1.1. General risk calculators

Several risk indices have been developed based on multivariable analyses of observational data and have been validated during the last decade (Table 6).^{47,49,76} Most risk calculators integrate both patient-related and surgery-related risk factors, but none of them include biomarkers among their variables. Calculators for most of the commonly used risk indices are available online (Table 6). The risk calculators can be used in addition, or as an alternative, to the assessment of surgery-related and patient-related risk factors described in Section 3.3. The Task Force decided against recommending one specific risk score. The Task Force also decided that the selection criteria for further pre-operative testing should be clinical criteria, and not based on a specific score.

Figure 3 Examples of questions and concerns expressed by patients.

^aThe RCRI was updated January 2019.

^bDakik et al. 2019, 2020, and 2022, and Msheik et al.^{49–51,81}

^cThe percentages relate to general surgeries.⁵⁰

The RCRI estimates the risk of 30 day mortality, MI, or cardiac arrest, and is based on six variables.^{46,47} It has been validated in several countries and is easy to use.⁴⁷ A score of 0 indicates a 4% risk of 30 day mortality, MI, or cardiac arrest; a

score of 1 indicates a 6% risk; a score of 2, 10%; and a score of ≥ 3 , 15%.⁴⁷

The American College of Surgery National Surgical Quality Improvement Program (ACS NSQIP) developed an interactive risk

calculator providing an estimate of the absolute 30 day probability of serious complications and any complications compared with the average patient.⁷⁶ Evaluated in the US surgical database, the ACS NSQIP model performed better than the RCRI, but an external validation in the Philippines found both to have excellent discriminative abilities for predicting any MACE.⁴⁸ The RCRI can be used without a web connection, whereas the ACS NSQIP is procedure-specific and is only available on the web. For clinical use, the RCRI is more accessible, but the ACS NSQIP offers procedure-specific absolute risk estimates, which are valuable in patient-guided decision-making. In vascular surgery, both risk calculators have shown moderate accuracy with an area under curve (AUC) of 0.64 (95% CI, 0.57–0.70) for ACS NSQIP and 0.60 (95% CI, 0.54–0.65) for RCRI, due to underestimation of the risk of MI. Attempts to generate procedure-specific vascular calculators have not given better predictions in validation cohorts.⁷⁷

The Surgical Outcome Risk Tool (SORT) estimates 30 day mortality after NCS based on the American Society of Anesthesiologists Physical Status (ASA–PS) grade, urgency of surgery, surgical speciality and severity, cancer, and age ≥65 years. In the validation study, combining subjective assessment with the SORT was significantly better than using either alone.^{78,79} The Surgical Risk Calculator is another tool that predicts intra-operative and 30 day risk of MI or cardiac arrest based on age, ASA–PS grade, pre-operative dependent functional status, creatinine, and type of surgery.⁸⁰

The American University of Beirut (AUB)-HAS2 Cardiovascular Risk Index is the most recently developed index to assess 30 day event risk (death, MI, or stroke), and stratifies patients undergoing NCS into low (score 0–1), intermediate (score 2–3), and high risk (score >3) based on six data elements (see Table 6); scores >3 denote a post-operative event rate of >10%.⁴⁹ The AUB-HAS2 Index has been tested in a broad spectrum of surgical subpopulations and demonstrated superior discriminatory power compared with the commonly utilized RCRI (Table 6).^{50,51,81}

There is significant variability in the predicted risk of cardiac complications using different risk-prediction tools; none can be disqualified with current evidence.⁸²

4.1.2. Frailty

Frailty is an age-related, multidimensional state of decreased physiological reserve that results in diminished resiliency, loss of adaptive capacity, and increased vulnerability to stressors.^{83,84} The peri-operative evaluation of elderly patients (>70 years) who require elective intermediate- or high-risk NCS should include frailty screening, which has proven to be an excellent predictor of unfavourable health outcomes in the older surgical population.

Frailty has a relevant impact on mortality and MI risk but does not add to risk estimation derived from the ACS NSQIP calculator, as frailty is associated with variables already in the main model. By adding six variables, the ACS NSQIP predicts the risk of post-operative delirium, functional decline, need of a new mobility aid, or pressure ulcer.⁸⁵ The use of this broader-inclusive score identifies cases that profit the most by involving a geriatrician in the pre- and post-operative team.^{86,87} A measure of frailty informs the patient and surgeon about further life expectancy and the chance of post-operative delirium, dependency of mobility support, and need of nursing home or other care support after planned surgery.

Of the available screening tools for frailty, the Frailty Index and the Frail Phenotype are the most commonly recommended.^{88,89} Of note, the Frailty Index includes cognitive testing, while both scores assess physical function.^{90,91} A simpler approach is offered by the Clinical Frailty Scale, which relies on information from the history taking. The Clinical Frailty Scale has been validated against the Frailty Index.⁸⁸ For cognitive screening to incorporate with the Frailty Index, Mini-Cog[®] is a simple and fast screening tool validated for pre-operative screening⁹² (Supplementary data, Figure S1, and Tables S2 and S3).

Once a diagnosis of frailty is confirmed, the prognosis of a frail patient can be improved by shared decision-making between at least a treating physician (e.g. surgeon), anaesthesiologist, geriatrician, the patient, and the patient’s relatives. During the shared decision-making process, a careful discussion with a frail patient about goals of care could help them to have realistic expectations and make better informed decisions before surgery. After a shared decision to go ahead with a planned NCS, multimodal pre-habilitation programmes—including exercise, nutrition, and psychological interventions—could potentially improve the peri-operative prognosis of frail patients by an individualized approach tailored to the patient’s baseline functional status, comorbidities, and cognitive/psychological function.⁹⁰

4.2. Functional capacity

Quantifying functional capacity has been a pivotal step in pre-operative cardiac risk assessment.¹⁰ Although the validity of interview-based assessment of functional capacity has been questioned,⁹³ a recent large prospective cohort study of high-risk patients undergoing NCS found self-reported inability to climb two flights of stairs added incremental value to the 30 day cardiac event rate when added to the RCRI.⁹⁴

Metabolic equivalents (METs) <4 have long been considered to indicate poor functional capacity; however, studies using METs have been based on subjective interviews and not shown proven value. In the Measurement of Exercise Tolerance before Surgery (METS) study, the Duke Activity Status Index (DASI) (<https://www.mdcalc.com/duke-activity-status-index-dasi#evidence>) had a more precise estimation of cardiac risk than subjectively assessed functional capacity, improving risk estimation using RCRI.⁹⁵ A DASI score <34 was associated with increased odds of 30 day death or MI.⁹⁶ From the DASI score, METs can be calculated as $VO_2 \text{ max (maximal oxygen consumption)}/3.5$; where $VO_2 \text{ max (mL/kg/min)} = 0.43 \times \text{DASI} + 9.6$. Furthermore, cardiopulmonary exercise testing (CPET) did not predict 30 day mortality, post-operative MI, or cardiac arrest.^{94,95} It should be noted that a relatively low number of primary outcome events limited the statistical power of the analysis.

Recommendation Table 6 — Recommendations for pre-operative assessment of frailty and functional capacity

Recommendations	Class ^a	Level ^b
In patients aged ≥70 years and scheduled to undergo intermediate- or high-risk NCS, frailty screening should be considered using a validated screening tool. ^{84–87,90,91}	Ila	B

^bLevel of evidence.

4.3. Electrocardiography

The 12-lead ECG is a widely available, simple, and inexpensive tool that is able to semi-quantitatively assess cardiac risk (e.g. Q waves indicative of previous MI), and detect unknown CV conditions requiring therapy (e.g. atrial fibrillation [AF] or AV-block).^{97–99} It is recommended to obtain a pre-operative 12-lead ECG in patients who are aged ≥ 65 years or have known CVD, CV risk factors, or

symptoms suggestive of cardiac disorders, and scheduled to undergo intermediate- or high-risk surgery. It is not recommended to routinely obtain a pre-operative ECG in low-risk patients undergoing low-risk NCS.¹⁰⁰

Comparison with previous ECG recordings is helpful whenever relevant abnormalities are identified. Pre-operative recording of ECG also enables identification of intra- and post-operative ECG changes.

4.4. Biomarkers

As the peri-operative risk for cardiac complications depends on the presence and extent of cardiac disease, widely available and simple biomarkers that detect and quantify essential prognostic aspects of cardiac involvement may aid in the evaluation. High-sensitivity cardiac troponin T/I (Hs-cTn T/I) quantifies myocardial injury, and BNP and NT-proBNP quantify haemodynamic cardiac wall stress (Figure 4).

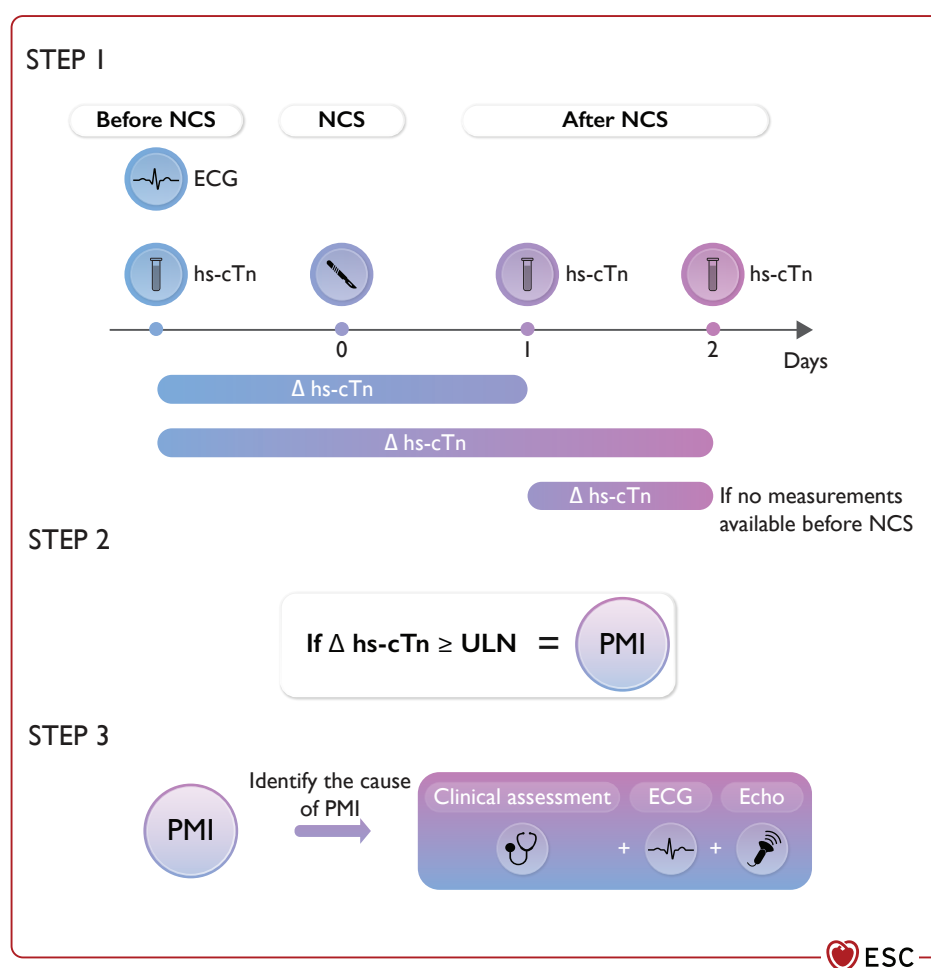

Figure 4 Recommended measurements to assess and detect the risk of post-operative cardiac complications. ECG, electrocardiogram; hs-cTn, high-sensitivity cardiac troponin; PMI, peri-operative myocardial infarction/injury; ULN, upper limit of normal. In patients scheduled to undergo intermediate- or high-risk surgery, pre-operative risk assessment is complemented by ECG, hs-cTn, and BNP/NT-proBNP. An absolute increase in hs-cTn concentration of more than the ULN on days 1 or 2 after surgery compared to the pre-operative level is defined as PMI.^{109–111} In the absence of a pre-operative hs-cTn T/I concentration, a very high hs-cTn T/I concentration on day 1 (e.g. more than five-times the ULN) or a relevant change from day 1 to day 2 (absolute increase or decrease more than the ULN vs. day 1) would also achieve a reliable diagnosis of PMI. Detection of PMI should trigger ECG recording and detailed clinical evaluation for PMI work-up and therapy. The differential diagnosis of PMI according to the fourth universal definition of MI is discussed in Section 8. The ESC 0/1/2 h algorithm has not been validated for the peri-operative setting and cannot be used here.

Both Hs-cTn T/I and BNP/NT-proBNP complement clinical assessment and ECG in risk prediction.^{9,52,53,101–103} Hs-cTn T/I and, to a lesser extent, BNP/NT-proBNP concentrations are higher in patients with stress-induced myocardial ischaemia vs. those without, and very low hs-cTn T/I concentrations achieve a very high negative predictive value to rule out myocardial ischaemia.^{104–107}

Several large prospective studies have shown that both hs-cTn T/I and BNP/NT-proBNP have high and incremental prognostic value for peri-operative cardiac complications, including CV death, cardiac arrest, acute HF, and tachyarrhythmias. In a cohort of nearly 1000 subjects undergoing major elective NCS, individuals with pre-operative hs-cTn T concentrations of >14 ng/L had an in-hospital mortality of 6.9% vs. 1.2% in patients with hs-cTn T concentrations ≤14 ng/L ($P < 0.001$; AUC 0.81).⁵³ In a large prospective cohort study including 10 402 patients from 16 centres, NT-proBNP improved risk prediction beyond the RCRI.⁵² Among 1923 patients undergoing NCS, NT-proBNP outperformed both RCRI and echocardiographic parameters in the prediction of peri-operative CV events.¹⁰³ Overall, hs-cTn T/I and BNP/NT-proBNP seem to have comparable accuracy in the prediction of cardiac complications.^{52,53,98–103,108} However, Hs-cTn T/I has four advantages over BNP/NT-proBNP: (i) it is more widely available; (ii) it is less expensive; (iii) if normal, it enables acute MI to be ruled out in the preceding days; and (iv) availability of pre-operative hs-cTn T/I concentration enables accurate diagnosis of PMI on Day 1 after surgery.^{109–111} See Section 8 for more details on diagnosis and treatment of PMI.

B-type natriuretic peptide/NT-proBNP has two advantages. First, if elevated, evidence from randomized controlled screening studies performed outside the peri-operative setting has supported the concept that BNP/NT-proBNP-triggered cardiac work-up and intensification of therapy improve outcomes.^{112,113} Second, HF is a frequently undiagnosed condition in the elderly population most often undergoing NCS.^{47,114} Interpreting BNP/NT-proBNP concentrations as quantitative markers of HF with evolving rule-in cut-offs may facilitate detection of HF, optimal intra-operative monitoring, and initiation or optimization of HF therapy after surgery.¹¹⁴

To date, there is insufficient evidence in support of other CV biomarkers for this specific indication.^{115,116}

Recommendation Table 7 — Recommendations for pre-operative risk assessment—electrocardiography and biomarkers

Recommendations	Class ^a	Level ^b
In patients who have known CVD or CV risk factors (including age ≥65 years), or symptoms or signs suggestive of CVD it is recommended to obtain a pre-operative 12-lead ECG before intermediate- and high-risk NCS. ^{97–99}	I	C
In patients who have known CVD, CV risk factors (including age ≥65 years), or symptoms suggestive of CVD it is recommended to measure hs-cTn T or hs-cTn I before intermediate- and high-risk NCS, and at 24 h and 48 h afterwards. ^{53,105–107,109–111,117}	I	B

Continued

In patients who have known CVD, CV risk factors (including age ≥65 years), or symptoms suggestive of CVD, it should be considered to measure BNP or NT-proBNP before intermediate- and high-risk NCS. ^{52,104,112–114}	IIa	B
In low-risk patients undergoing low- and intermediate-risk NCS, it is not recommended to routinely obtain pre-operative ECG, hs-cTn T/I, or BNP/NT-proBNP concentrations. ^{109,111,117–119}	III	B

© ESC 2022

BNP, B-type natriuretic peptide; CV, cardiovascular; CVD, cardiovascular disease; ECG, electrocardiogram; hs-cTn I, high-sensitivity cardiac troponin; hs-cTn T, high-sensitivity cardiac troponin T; NCS, non-cardiac surgery; NT-proBNP, N-terminal pro-BNP; ULN, upper limit of normal.

Abnormal ECG: pathological Q wave, ST-T wave changes, non-sinus rhythm, left bundle branch block. Abnormal pre-operative hs-cTn T/I: more than ULN. Age, sex, and known cardiac disease should also be considered when interpreting the pre-operative concentration.⁹⁸

Abnormal BNP: ≥35 pg/mL; abnormal NT-proBNP: ≥125 pg/mL. BNP/NT-proBNP should be interpreted as quantitative markers of heart failure, and also take into account age, sex, obesity, and known cardiac disease.^{52,114} Please note that age, renal dysfunction, and obesity are important confounders in the age group in which measurement of BNP/NT-proBNP is recommended, while sex has less impact.

^bLevel of evidence.

4.5. Non-invasive and invasive procedures

4.5.1. Resting transthoracic echocardiography

In large retrospective cohorts, routine pre-operative TTE before high-risk NCS did not reduce the risk of post-operative MACE or provide more information than clinical risk models.^{120–122} Poor exercise tolerance, abnormal ECG, suspected new or significant CVDs without follow-up within the last 90 days, unexplained dyspnoea, or coexisting clinical risk factors are appropriate indications for TTE.^{123,124} Pre-operative TTE provides information on three main risk markers for post-operative cardiac events: LV dysfunction, VHDs, and cardiomyopathies. Left ventricular systolic dysfunction is an important predictor of post-operative HF.¹²⁵ However, low ventricular ejection fraction is a borderline independent predictor of major post-operative CV complications.^{126–128}

Pre-operative FOCUS examination—with a hand-held ultrasound device for the assessment of murmurs, haemodynamic instability, ventricular function, and dyspnea—may impact patient management by improving the diagnostic accuracy of clinical assessment, and help to triage candidates for standard TTE, plan surgery and anaesthesia technique, and with post-operative monitoring.^{129–131} However, current evidence remains mostly confined to uncontrolled or retrospective observational studies with no clear benefits on the outcome, despite a favourable impact on peri-operative management.^{130,132} In a multicentre randomized trial, preliminary results showed that pre-operative FOCUS significantly reduced all-cause mortality.¹³³ Notably, because of the lack of spectral Doppler capabilities, the FOCUS examination is only accurate for assessing main structural and functional abnormalities.

Patients with diastolic dysfunction are usually old, more hypertensive, obese, diabetic, and likely to have AF or chronic renal disease. Several studies with different clinical end-points have underlined

the association of diastolic dysfunction with post-operative adverse events, including pulmonary oedema, AF, and mortality.^{134–138} A meta-analysis including 3876 patients undergoing NCS found pre-operative diastolic dysfunction to be an independent risk factor for pulmonary oedema, congestive HF, and MI after surgery.¹³⁹ However, a recent retrospective study, including 7312 patients, showed no association between the degree of diastolic dysfunction and in-hospital mortality or hospital length of stay in NCS patients.¹⁴⁰ Awareness of diastolic dysfunction or high LV filling pressure (e.g. pulmonary hypertension, left atrial volume, E/e' ratio) seems necessary to optimize peri-operative patient management; however, evidence does not support screening for diastolic dysfunction.

Recommendation Table 8 — Recommendations for transthoracic echocardiography

Recommendations	Class ^a	Level ^b
TTE is recommended in patients with poor functional capacity ^c and/or high NT-proBNP/BNP, ^d or if murmurs are detected before high-risk NCS, in order to undertake risk-reduction strategies. ^{121,124,127,141–143}	I	B
TTE should be considered in patients with suspected new CVD or unexplained signs or symptoms before high-risk NCS. ^{59,124,125}	IIa	B
TTE may be considered in patients with poor functional capacity, abnormal ECG, high NT-proBNP/BNP, ^d or ≥ 1 clinical risk factor before intermediate-risk NCS. ^{126–128}	IIb	B
To avoid delaying surgery, a FOCUS exam performed by trained specialists may be considered as an alternative to TTE for pre-operative triage. ^{129,130,132,133,144}	IIb	B
Routine pre-operative evaluation of LV function is not recommended. ^{122,145}	III	C

BNP, B-type natriuretic peptide; CVD, cardiovascular disease; ECG, electrocardiogram; FOCUS, focused cardiac ultrasound; LV, left ventricular; NCS, non-cardiac surgery; NT-proBNP, N-terminal pro-B-type natriuretic peptide; TTE, transthoracic echocardiography.

^d ≥ 125 pg/mL/35 pg/mL.

4.5.2. Stress tests

4.5.2.1. Exercise stress test

Physical exercise, using a treadmill or bicycle ergometer, provides an estimate of functional capacity, evaluates blood pressure (BP) and heart rate response, and detects myocardial ischaemia through pathological ST-segment changes with poor sensitivity (61–73%) and specificity (60–80%).¹⁴⁶ An exercise stress test alone should only be considered a valuable alternative to diagnose obstructive CAD if non-invasive imaging tests are unavailable.¹⁴⁶ An exercise stress test is of no diagnostic value in patients with pre-existing ST-segment abnormalities (i.e. left bundle branch block, paced

rhythm, Wolff–Parkinson–White [WPW] syndrome, ≥ 0.1 mV ST-segment depression on resting ECG, or taking digitalis). In addition, an exercise test is unsuitable for patients with limited exercise capacity, owing to their inability to reach their target heart rate. Therefore, an exercise stress test alone should only be considered a valuable alternative to diagnose obstructive CAD if non-invasive imaging tests are unavailable, or for assessing functional capacity when clinical history is ambiguous.¹⁴⁶

4.5.2.2. Stress imaging

The use of stress imaging is appropriate for risk assessment in patients with clinical risk factors and poor functional capacity.^{147,148} The choice of the test is driven by local expertise. Selection, optimal, and safe performance of stress imaging should comply with related guidelines and recommendations.^{146,148,149} Stress imaging is not recommended in patients undergoing urgent surgery or with an unstable clinical condition. Evidence on the role of stress imaging for peri-operative risk prediction and patient management is largely based on inducible ischaemia by pharmacological stress testing, although no evidence indicates the superiority of pharmacological stress to exercise stress imaging in patients who are able to perform an adequate level of physical exercise. Several studies and meta-analyses have consistently defined clinical utility of pharmacological stress imaging for peri-operative risk assessment in patients undergoing NCS.^{150–154} Although RCTs related to post-operative outcome are lacking, there are large-scale prospective studies showing a risk-adjusted association of stress imaging results with peri-operative cardiac complications.^{155–157}

Studies and meta-analyses have demonstrated similar prognostic value of stress echocardiography and myocardial perfusion imaging for peri-operative risk assessment with slightly higher negative predictive value of stress echocardiography,¹⁵² but the overall accuracy varies with ischaemic heart disease (IHD) prevalence.¹⁵¹ A moderate-to-large perfusion defect on either test is highly sensitive for post-operative cardiac events.^{152,158} Normal stress imaging exams without resting abnormalities have high negative predictive value.^{159,160} However, positive predictive value of stress imaging for peri-operative cardiac events is relatively low and requires confirmation by other tests.^{150,152,161}

In a recent retrospective study including 4494 patients, dobutamine stress echocardiography (DSE) provided modest incremental predictive value for peri-operative CV complications over clinical variables and was found to be useful as part of a stepwise approach in the risk stratification of patients undergoing intermediate- to high-risk NCS.¹⁵⁷ The strongest predictors of post-operative adverse events determined so far are significant ischaemia (more than four ventricular segments) during DSE, ischaemic threshold (60% of age-predicted maximal heart rate), and a history of congestive HF.^{162,163}

A negative DSE without resting wall motion abnormality has excellent negative predictive value, even when target heart rate cannot be achieved despite an aggressive DSE regimen.¹⁶⁴ In asymptomatic patients if functional capacity is unknown, stress echocardiography also enables dynamic evaluation of LV systolic and diastolic function; valvular diseases such as aortic valve stenosis (AS), mitral valve stenosis (MS), and hypertrophic obstructive cardiomyopathy; and pulmonary hypertension.¹⁶⁵ However, the role of DSE for risk

estimation in non-ischæmic heart diseases before NCS has yet to be studied.

Myocardial perfusion imaging is particularly suitable if patients have poor acoustic windows for DSE. Meta-analyses of patients undergoing major NCS have demonstrated that, compared with fixed defects, reversible perfusion defects were associated with higher risk of cardiac death or non-fatal MI. The risk of cardiac events correlates with the extent of reversible perfusion abnormalities (severe: >20% of myocardium). Normal myocardial perfusion imaging in high-risk patients identifies a low-risk subgroup comparable with those without clinical risk factors for adverse cardiac outcomes.^{154,159,160}

Stress cardiac magnetic resonance (CMR) imaging and late gadolinium enhancement are also accurate tools for detection of IHD and prognostication.¹⁶⁶

Recommendation Table 9 — Recommendations for stress imaging

^dPre-test probability >15% based on age, sex, and nature of symptoms, or two or more risk factors for CVD (dyslipidaemia, diabetes, hypertension, smoking, family history of CVD), or resting ECG changes (Q wave or ST-segment/T wave changes), or LV dysfunction suggestive of CAD.¹⁴⁶

^eOne or more clinical risk factor according to the Revised Cardiac Risk Index (ischæmic heart disease, cerebrovascular disease, history of congestive heart failure, serum creatinine level >2 mg/dL, diabetes requiring insulin therapy).^{46,47}

4.5.3. Angiography

4.5.3.1. Coronary computed tomography angiography

Coronary computed tomography angiography (CCTA) is recommended as an initial test for diagnosing CAD in stable patients with a low clinical likelihood or no previous diagnosis of CAD, and characteristics associated with a high likelihood of good image quality.¹⁴⁶ In addition, CCTA is recommended as an alternative to invasive coronary angiography (ICA) for excluding non-ST-segment elevation acute coronary syndrome (NSTEMI-ACS) when there is low-to-intermediate likelihood of CAD, and when cardiac troponin and/or ECG are normal or inconclusive.⁹⁸ The practical utility of CCTA is reduced when a high coronary calcium score is present.¹⁶⁷

In patients undergoing NCS, the role of pre-operative CCTA to rule out CAD has been investigated in small- to medium-sized observational studies. The Coronary Computed Tomographic Angiography and Vascular Events in Noncardiac Surgery Patients Cohort Evaluation (Coronary CTA VISION) trial prospectively investigated the incremental predictive value of CCTA over RCRI in 955 patients with a history of or risk factors for CAD, or a history of congestive HF undergoing NCS.¹⁶⁸ Coronary computed tomography angiography improved the risk estimation for the primary outcome of post-operative CV death and non-fatal MI within 30 days, although CCTA was associated with more than five times inappropriate risk overestimations among patients not experiencing the primary outcome. The predictive value of CCTA further improved when associated with non-invasive functional testing, such as myocardial perfusion imaging, with a positive and negative predictive value of 50% (95% CI, 21–79) and 100% (95% CI, 79–100), respectively.¹⁶¹

Coronary computed tomography angiography associated with additional functional assessment of coronary stenosis with fractional flow reserve (FFR) with computed tomography (CT) was able to identify functionally severe coronary stenosis in 57% of the asymptomatic patients with no history of cardiac disease undergoing carotid endarterectomy (CEA).¹⁶⁹ In 135 asymptomatic patients with no history of cardiac disease undergoing peripheral vascular surgery, pre-operative FFR with CT facilitated the identification of functionally severe coronary stenosis in 53% of the patients. These patients benefited from further revascularization, with a 1 year lower rate of CV death and MI.¹⁷⁰

4.5.3.2. Invasive coronary angiography

There is a lack of information from RCTs relating to the usefulness of ICA in patients scheduled for NCS. Adopting an ICA assessment may also cause an unnecessary and unpredictable delay in an already planned surgical intervention, and adding an independent procedural risk to the overall risk. Despite the fact that CAD may be present in a significant number of patients requiring NCS, indications for pre-operative coronary angiography and revascularization are similar to angiography indications in the non-surgical setting.^{98,146,171} Pre-operative treatment of patients with myocardial ischaemia, either medically or with intervention, is recommended.

Recommendation Table 10 — Recommendations for coronary angiography

Recommendations	Class ^a	Level ^b
It is recommended to use the same indications for ICA and revascularization pre-operatively as in the non-surgical setting. ^{98,146}	I	C
CCTA should be considered to rule out CAD in patients with suspected CCS or biomarker-negative NSTEMI-ACS in case of low-to-intermediate clinical likelihood of CAD, or in patients unsuitable for non-invasive functional testing undergoing non-urgent, intermediate-, and high-risk NCS.	IIa	C

5. General risk-reduction strategies

5.1. Cardiovascular risk factors and lifestyle interventions

Control of CV risk factors—including BP, dyslipidaemia, and diabetes—is important before NCS. For pre-operative management of BP and diabetes, see [Sections 6.8 and 6.13](#), respectively.

While lifestyle modifications before intervention reduce the risk of several peri-operative complications, the impact on CV complications has not been adequately explored. Of the lifestyle changes recommended before surgery, smoking cessation is the best documented in RCTs. Smoking has been associated with a higher rate of post-operative complications at 30 days.^{173,174} Reviews of RCTs have shown an effect of smoking cessation up to 6 months post-operatively, with a clear reduction in any post-operative complications by hazard ratio (HR) 0.42 (95% CI, 0.27–0.65), particularly wound infections (HR, 0.43; 95% CI, 0.21–0.85).^{173,175} Regarding timing of cessation, reviews of observational studies have shown consistent associations with better surgical outcome for cessation >4 weeks before surgery, with each additional week resulting in a further improvement of 19%.^{176–178}

Pre-operative exercise programmes have only been tested in small RCTs, and recent reviews have shown a relative risk (RR) reduction in post-operative complications of 67% (RR, 0.33; 95% CI, 0.17–0.61).¹⁷⁹ Referral to a pre-operative exercise programme may be considered for patients scheduled for major or complex elective surgery.^{176,179,180} Weight reduction of obese patients immediately prior to surgery is not recommended.

Recommendation Table 11 — Recommendations for lifestyle and cardiovascular risk factors

5.2. Pharmacological

5.2.1. Beta-blockers

Beta-blockers reduce myocardial oxygen consumption by reducing contractile force and heart rate. Beta-blockers are also effective anti-arrhythmic agents. In addition, some beta-blockers such as metoprolol have an effect on acute inflammatory responses by inhibiting neutrophil hyperactivation in acute settings.¹⁸⁴ These properties mean that beta-blockers have been some of the most frequently tested cardioprotective agents in patients undergoing NCS. Several RCTs have evaluated the effects of peri-operative beta-blockade on clinical end-points in patients with different risk profiles (see [Supplementary data, Section 3.1.1](#)). Type, dosing and titration, timing of initiation, duration of beta-blocker therapy, type of surgery, and risk profile of subjects significantly differ between studies, making comparisons complex.

The question about pre-surgery initiation of beta-blockers has been a matter of intense controversy (see [Supplementary data, Section 3.1.1.1](#)). The largest and latest trial on the topic, the Perioperative Ischemic Evaluation (POISE-1) trial, enrolled 8351 patients with or at risk of atherosclerotic disease, and not on beta-blockers before NCS. Patients were randomized to extended-release metoprolol succinate 200 mg daily or placebo.¹⁸⁵ Treatment was initiated 2–4 h before surgery and maintained for 30 days. The primary outcome (composite of CV death, non-fatal MI, and non-fatal cardiac arrest) was significantly lower in the metoprolol arm (5.8% vs. 6.9% [$P=0.04$]). Metoprolol was associated with significant reductions in MIs, coronary revascularizations, and AF. However, the incidences of all-cause death, stroke, and clinically significant hypotension or bradycardia were significantly higher in the metoprolol arm. Post hoc analysis showed that hypotension carried the greatest attributable risk of death and stroke.¹⁸⁶ The high dose of extended metoprolol might have played a role in the adverse events seen at follow-up.

Several meta-analyses, systematic reviews, and observational studies have also been reported (see [Supplementary data, Table S4](#)).^{187–189} Overall, initiation of beta-blockers before NCS was not associated with a net clinical benefit in most analyses, but they might be beneficial in patients with high CV risk profiles or who are undergoing high-risk surgical interventions (including vascular interventions).^{188,190–192} When oral beta-blockade is initiated in CAD patients who undergo NCS, the use of atenolol or bisoprolol as a first choice may be considered.^{190,193–195}

In patients who are on chronic beta-blocker therapy before surgery, it is recommended to maintain these in the peri-operative period. Increased mortality following pre-operative beta-blocker withdrawal has been reported in five observational studies.^{190,196–199} Interruption of this therapy for >2 days post-operatively may double the risk of AF.²⁰⁰

Post-operative tachycardia should initially lead to treatment of the underlying cause—such as hypovolaemia, pain, blood loss, or infection—rather than simply increasing the beta-blocker dose. When beta-blockers are indicated, the optimal duration of the peri-operative beta-blockade cannot be derived from randomized trials.

According to a meta-analysis of RCTs including 14 967 patients, beta-blockers can reduce the risk of post-operative AF after NCS;²⁰¹ however, this comes at the cost of an increased risk of bradycardia, hypotension, and stroke.¹⁸⁷

The ultra-short-acting beta-blockers esmolol and landiolol have the theoretical advantages of very fast onset of effects and short half-lives. Notably, landiolol may lower BP to a lower extent than esmolol. Evidence of prevention of AF with landiolol after NCS is less robust and inconsistent than in the context of cardiac surgery.^{202–205} The timing of the initiation of beta-blockers to prevent AF remains unclear, with most prophylactic regimens using short-acting agents being started intra-operatively.¹⁸⁷

5.2.2. Amiodarone

Amiodarone is the most frequently used agent for prevention of post-operative AF,²⁰⁶ with a risk reduction of 58% in NCS in a meta-analysis evaluating different antiarrhythmic drugs (AADs), but may induce relevant non-cardiac side effects.²⁰¹ In another meta-analysis, amiodarone (oral or intravenous [i.v.]) and beta-blockers were equally effective in reducing post-operative AF.²⁰⁷ In another prospective RCT, a combination of beta-blocker plus amiodarone outperformed beta-blockers alone in reducing post-operative AF.²⁰⁸ It should be noted that the two latter studies were undertaken in patients undergoing cardiac surgery.

Overall, while preventive amiodarone seems to reduce the incidence of AF, the clinical benefits associated with its routine use are unclear.

5.2.3. Statins

Despite the wide-ranging use of statins in patients undergoing surgery, RCTs assessing the effects of initiating statin therapy during the peri-operative period are scarce. This should be viewed separately from patients already on statin therapy. The long-term use of statins in patients with CVD or high risk of CVD is well-established.⁴⁰

Observational data suggest a potential benefit of statins in the peri-operative phase. In a large, retrospective, and observational cohort, which included 180 000 veterans undergoing NCS, the use of statins on the day of or the day after surgery was associated with a reduction in mortality (RR, 0.82; 95% CI, 0.75–0.89).²⁰⁹ Similar results were seen in a retrospective cohort study using hospital discharge and pharmacy records.²¹⁰ Although both studies used propensity matching to reduce bias, these analyses are prone to confounding, especially when discharge and pharmacy records are used. As such, RCTs give a more reliable effect estimation, for example: the Lowering the Risk of Operative Complications Using Atorvastatin Loading Dose (LOAD) trial studied 648 statin-naïve patients, of whom 24% had a history of CVD and 49% had diabetes.²¹¹ In this randomized, placebo-controlled trial, patients received a loading dose of atorvastatin 80 mg within 18 h before surgery followed by 40 mg daily for 7 days. Use of atorvastatin did not reduce the risk of major events (all-cause mortality, non-fatal MI, or stroke at 30 days [HR, 0.87; 95% CI, 0.60–1.26; $P=0.46$]). However, the trial was underpowered to draw definite conclusions. In addition, several meta-analyses have shown ambiguous results and most studies are of a limited size with less than 100 patients.^{212,213}

Therefore, routine peri-operative initiation of statin therapy is not recommended. However, in patients in whom statin use is already indicated, treatment should be considered peri-operatively, particularly in patients scheduled for high-risk surgery (e.g. vascular surgery).

5.2.4. Renin–angiotensin–aldosterone system inhibitors

Data on peri-operative use of renin–angiotensin–aldosterone system (RAAS) inhibitors are inconclusive. The majority of studies suggest that continued use of RAAS inhibitors is associated with a higher risk of peri-operative hypotension and, as a consequence, higher use of vasopressors and inotropes. Furthermore, intra-operative hypotension and its duration is associated with end-organ damage, including kidney injury, myocardial damage, and stroke.²¹⁴ In a small trial of 275 subjects, randomized to either continuation of their angiotensin-converting-enzyme inhibitors (ACEIs) or omission of the final pre-operative ACEI dose, patients randomized to omission of the last dose before surgery experienced intra-operative hypotension less frequently (76/137 [55%] vs. 95/138 [69%]) and vasopressor use was less likely.²¹⁵ On the other hand, post-operative hypertension was more frequent in the omission group. Furthermore, in an observational cohort study consisting of 4802 patients undergoing NCS and using an ACEI or angiotensin receptor blocker (ARB), discontinuation of these drugs in the 24 h before surgery was associated with a lower risk of intra-operative hypotension (adjusted RR, 0.80; 95% CI, 0.72–0.93; $P<0.001$), and associated with a reduction in the composite end-point consisting of all-cause mortality, stroke, and MI (adjusted RR, 0.82; 95% CI, 0.70–0.96; $P=0.01$).²¹⁶ 8% of the patients in this cohort were diagnosed with HF, in whom RAAS inhibitors are the cornerstone of medical therapy. A systematic review, including nine studies (five RCTs and four cohort studies), revealed that withholding ACEI/ARB on the morning of surgery was not associated with mortality or MACE;²¹⁷ however, it did confirm that withholding therapy was associated with less intra-operative hypotension (OR, 0.63; 95% CI, 0.47–0.85). If an ACEI/ARB is withheld prior to NCS, it should be restarted as soon as possible in order to prevent unintended long-term omission. No data on peri-operative effects of angiotensin receptor neprilysin inhibitors (ARNI) exist, but hypotension is more common compared with patients on ACEI.²¹⁸

Some important RCTs in this field are ongoing: the impact of renin–angiotensin system inhibitors continuation vs. discontinuation on outcome after major surgery trial STOPorNOT²¹⁹ (NCT03374449), and the POISE-3 trial (NCT03505723) are both assessing a hypotension-avoidance strategy vs. a hypertension-avoidance strategy on the risk of vascular death and major vascular events in patients who are followed for 30 days after NCS.

5.2.5. Calcium channel blockers

The effects of calcium channel blockers (CCBs) on the balance between myocardial oxygen supply and demand makes them theoretically suitable for risk-reduction strategies. The relevance of randomized trials assessing the peri-operative effects of CCBs is limited by their small size, lack of risk stratification, and the absence of systematic reporting of cardiac death and MI. A meta-analysis pooled 11 randomized trials totalling 1007 patients.²²⁰ Treatment with CCBs significantly reduced the number of episodes of myocardial ischaemia and supraventricular tachycardia (SVT) in the pooled analyses. However, the decrease in mortality and MI reached statistical significance only when both end-points were combined (RR, 0.35; 95% CI, 0.08–0.83; $P=0.02$). In contrast, a matched case-control study of 1000 patients undergoing acute or elective

aortic aneurysm surgery suggested that dihydropyridine use was independently associated with an increased incidence of peri-operative mortality.²²¹ These observational data may be biased by the indications for the use of CCBs. In patients already on CCBs, particularly in those with vasospastic angina, it is recommended to continue CCBs during the peri-operative period, but withholding the dose on the day of surgery in order to avoid post-operative hypotension.

5.2.6. Alpha-2 receptor agonists

Alpha-2 receptor agonists reduce post-ganglionic noradrenaline output and might therefore reduce catecholamine surge during surgery. The European Mivazerol trial randomized 1897 patients with IHD who underwent intermediate- or high-risk NCS.²²² Mivazerol did not decrease the incidence of death or MI in the whole population. However, it did decrease the incidence of death in a subpopulation of 904 patients undergoing vascular surgery.²²² The international Peri-Operative ISchemic Evaluation 2 (POISE-2) trial randomized 10 010 patients undergoing NCS to clonidine or placebo.²²³ Clonidine did not reduce the rate of death or non-fatal MI in general or in patients undergoing vascular surgery (RR, 1.08; 95% CI, 0.93–1.26; $P=0.29$), but it did increase the risk of clinically important hypotension (RR, 1.32; 95% CI, 1.24–1.40; $P<0.001$) and non-fatal cardiac arrest (RR, 3.20; 95% CI, 1.17–8.73; $P=0.02$).

5.2.7. Diuretics

Diuretics are frequently used in patients with hypertension or HF. In general, therapy for treatment of hypertension should be continued to the day of surgery and resumed orally when possible. However, the benefit for continuing diuretics as antihypertensive therapy is unclear, and alternative antihypertensive agents may be considered. In HF, the dosage of diuretics should be adjusted well in advance for an optimal fluid balance before surgery, and to avoid fluid retention or dehydration.

The possibility of electrolyte disturbance should be considered in any patient receiving diuretics. Hypokalaemia is reported to occur in up to 36% of patients undergoing surgery (mostly NCS).^{224,225} Special attention should be given to patients prone to developing arrhythmias. Any electrolyte disturbance, especially hypokalaemia and hypomagnesaemia, should be corrected in due time before surgery. Acute pre-operative repletion in asymptomatic patients may be associated with more risks than benefits; thus, minor asymptomatic electrolyte disturbances should not delay acute surgery.

In the peri-operative period, volume status in patients with HF should be carefully monitored and optimized by loop diuretics or fluids. However, retrospective data suggest that intra-operative prescription of diuretics may increase the risk of acute kidney injury (AKI) after NCS.²²⁶

5.2.8. Ivabradine

Heart rate is an independent and modifiable risk factor for periprocedural MI (and maybe death) after NCS. Ivabradine is a negative chronotropic agent without associated hypotensive effect, and is

therefore a possible alternative to beta-blockers. However, there are few studies about the value of ivabradine for high-risk patients undergoing NCS.²²⁷ The small (78 patients) PeRi-OperaTivE CardioproTectiOn With Ivabradine in Non-cardiac Surgery (PROTECTIN) (NCT04436016) trial is ongoing.

5.2.9. Sodium–glucose co-transporter-2 inhibitors

The use of sodium–glucose co-transporter-2 (SGLT-2) inhibitors is increasing, due to proven CV benefits for patients with type-2 diabetes mellitus (DM) and a beneficial effect on outcomes for patients with HF and renal insufficiency. Euglycaemic diabetic ketoacidosis (EDKA) is a rare but serious complication. While the incidence was not significantly increased with SGLT-2 inhibitors in RCTs, several case reports indicate that EDKA may occasionally occur after (non-cardiac) surgery in patients on SGLT-2 inhibitors.²²⁸ A systematic review indicated that precipitating factors include diabetes medication changes, diet modifications, and intercurrent illnesses.²²⁹ The US Food and Drug Administration (FDA) recommends interrupting SGLT-2 inhibitor therapy for at least 3–4 days before scheduled surgery and to be vigilant for symptoms related to EDKA, prompting measurement of ketones.

Recommendation Table 12 — Recommendations for pharmacological treatment

Recommendations	Class ^a	Level ^b
Initiation		
In patients with an indication for statins, it should be considered to initiate statins peri-operatively.	IIa	C
Pre-operative initiation of beta-blockers in advance ^c of high-risk NCS may be considered in patients who have two or more clinical risk factors, ^d in order to reduce the incidence of peri-operative myocardial infarction. ^{188,190–192}	IIb	A
Pre-operative initiation of beta-blocker in advance of NCS may be considered in patients who have known CAD or myocardial ischaemia. ^{e,230–232}	IIb	B
Routine initiation of beta-blocker peri-operatively is not recommended. ^{185,187,189,233,234}	III	A
Continuation		
Peri-operative continuation of beta-blockers is recommended in patients currently receiving this medication. ^{190,196–199}	I	B
In patients already on statins, it is recommended to continue statins during the peri-operative period. ²³⁵	I	B
In patients with stable HF, peri-operative continuation of RAAS inhibitors may be considered.	IIb	C

Continued

Interruption		
In patients without HF, withholding RAAS inhibitors on the day of NCS should be considered to prevent peri-operative hypotension. ^{215,216}	Ila	B
For patients on diuretics to treat hypertension, transient discontinuation of diuretics on the day of NCS should be considered. ²³⁶	Ila	B
It should be considered to interrupt SGLT-2 inhibitor therapy for at least 3 days before intermediate- and high-risk NCS.	Ila	C

^dIschaemic heart disease, cerebrovascular disease, renal insufficiency, or diabetes mellitus, according to the RCRI score.²³⁹

^eTreatment should ideally be initiated between 30 and (at least) 2 days before surgery, starting at a low dose, and should be continued post-operatively.^{197,230,237}

5.3. Peri-operative handling of antithrombotic agents

Management of patients taking antithrombotic agents and needing surgery or an invasive procedure should consider patient- and procedure-related risk of bleeding and thrombosis. Furthermore, the pharmacokinetic and pharmacodynamic characteristics of the

antithrombotic drugs in use must be considered (Tables 7 and 8). The risk of bleeding associated with different types of interventions is shown in Table 9. Risk estimation and decision-making in patients requiring long-term antithrombotic therapy is challenging, since relevant associations exist between peri-operative antithrombotic management, bleeding, thrombotic events (MI and stroke), and mortality.^{6,11–13} Thus, interdisciplinary risk assessment ahead of the intervention is crucial, in order to classify the patient-related ischaemic and bleeding risks (e.g. cardiologist, neurologist, vascular specialist, and haematologist), and the surgical risk (surgeon and anaesthesiologist). Information on timing of intervention by indicated duration of antithrombotic therapy should be communicated with the patient and treating general physician.

5.3.1. Antiplatelets

5.3.1.1. Single antiplatelet therapy

In patients taking aspirin for primary prevention, the risk of ischaemic events is low and aspirin can be withdrawn prior to NCS. Permanent discontinuation should be considered post-operatively in low- and moderate-risk atherosclerotic cardiovascular disease (ASCVD) risk patients and/or in patients with high bleeding risk based on negative/neutral trials and the recommendations for primary prevention of CVD in the 2021 ESC Guidelines on cardiovascular disease prevention in clinical practice.^{40,241}

Due to the better risk–benefit ratio, aspirin has an established role for the long-term prevention of new cardiovascular events in patients with established CVD.²⁴² The POISE-2 trial is the largest, randomized, placebo-controlled trial of peri-operative aspirin in patients undergoing NCS.²⁴³

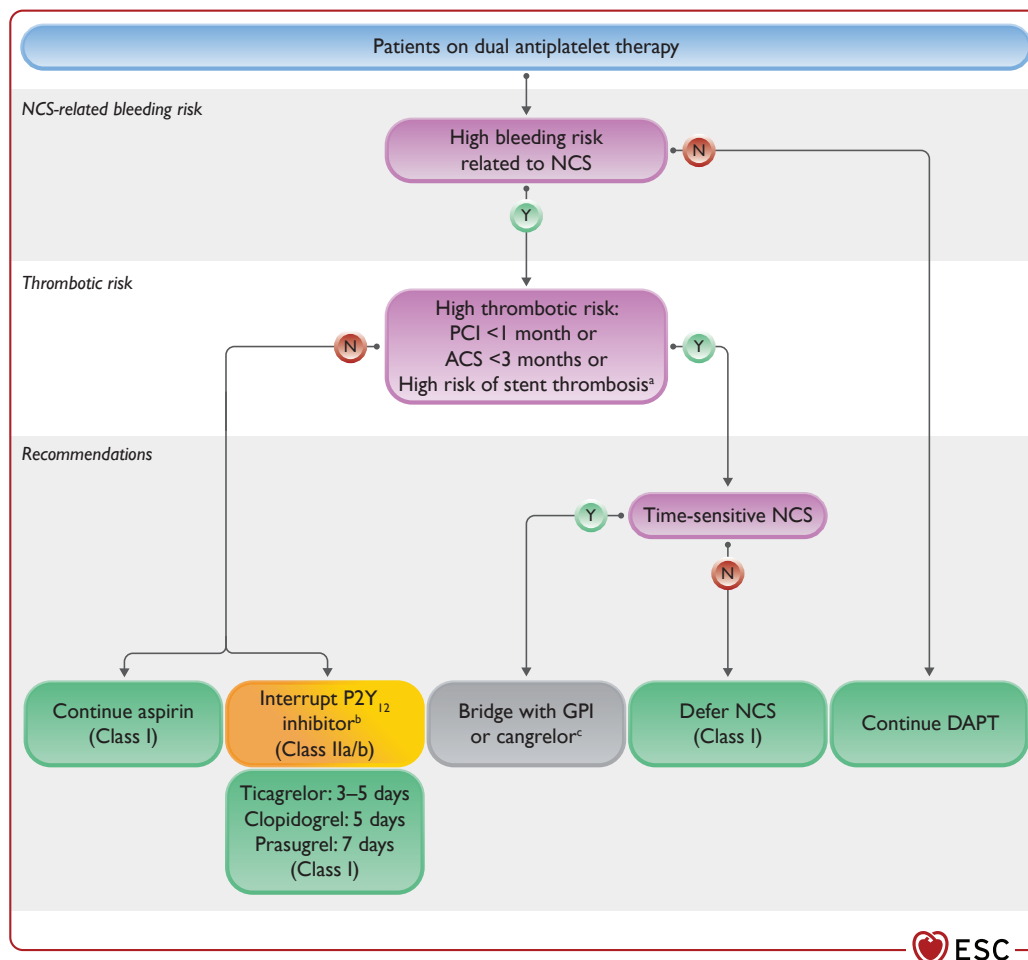

Figure 5 Recommendations for management of antiplatelet therapy in patients undergoing non-cardiac surgery. ACS, acute coronary syndrome; DAPT, dual antiplatelet therapy; GPI, glycoprotein IIb/IIIa inhibitors; PCI, percutaneous coronary intervention; N, no; NCS, non-cardiac surgery. Y, yes; ^aHigh risk of peri-operative stent thrombosis defined by at least one of the following: history of stent thrombosis under antiplatelet therapy, reduced left ventricular ejection fraction (<40%), poorly controlled diabetes, severely impaired renal function/haemodialysis, recent complex PCI (i.e. severely calcified lesion, left main PCI, chronic total occlusion, bifurcational/crush technique, bypass graft PCI), or stent malapposition/residual dissection. ^bTiming of resumption after interdisciplinary risk assessment as soon as possible (within 48 h) after surgery. ^cFor dosing, see Figure 7.

The trial randomized 10 010 patients undergoing NCS with established CVD, or who were at increased CV risk, to aspirin or placebo. Patients were stratified according to whether they had not been taking aspirin before the study or were already on aspirin; 33% of the patients had known vascular disease (23% CAD, 9% PAD, and 5% stroke). Aspirin did not reduce the rates of death or non-fatal MI at 30 days (7.0% vs. 7.1% in the placebo group [HR, 0.99; 95% CI, 0.86–1.15; $P=0.92$]). Major bleeding was more common in the aspirin group than in the placebo group (4.6% vs. 3.8% [HR, 1.23; 95% CI, 1.01–1.49; $P=0.04$]). The primary outcome results were similar, irrespective of whether or not patients had been taking aspirin before the study, and were also similar in patients with and without vascular disease.

In a post hoc analysis of 470 patients (<5%) who had undergone previous PCI, aspirin use was associated with a significant reduction in death or MI (HR, 0.50; 95% CI, 0.26–0.95; $P=0.036$) and MI alone (HR, 0.44; 95% CI, 0.22–0.87; $P=0.021$), while the risk of major or life-threatening bleeding was not significantly increased in this setting.²⁴⁴ Although the analysis carries several limitations, it supports

the perception that the ischaemic benefit of peri-operative aspirin use outweighs the bleeding risk in patients with previous PCI. Thus, among patients with previous PCI, in the absence of a very high bleeding risk, low-dose aspirin should be continued during the peri-operative period.

In patients undergoing transcatheter aortic valve implantation (TAVI) who have no other indication for oral anticoagulant (OAC) therapy, low-dose aspirin has been recommended as standard therapy by recent guidelines based on an RCT.^{245,246} There are no randomized data available assessing the withdrawal vs. continuation of aspirin in patients after TAVI on aspirin alone undergoing NCS.

If the bleeding risk outweighs the potential CV benefit, aspirin should be discontinued. For patients with high peri-operative bleeding risk (e.g. undergoing spinal surgery or certain neurosurgical or ophthalmological operations) aspirin should be discontinued for at least 7 days.

On rare occasions, chronic coronary syndrome (CCS) patients might be on clopidogrel monotherapy due to the results of recent trials²⁴⁷ and the recommendations of the 2020 ESC Guidelines for

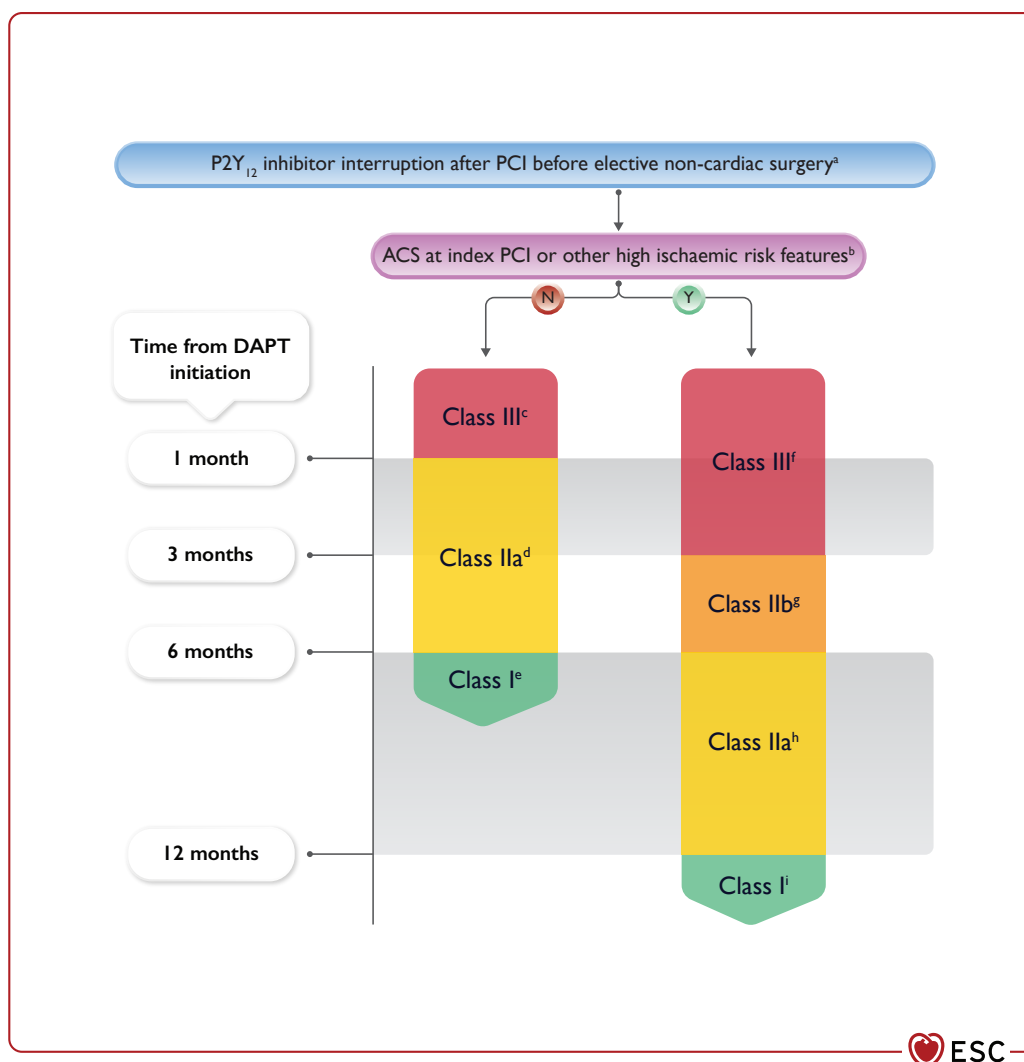

Figure 6 P2Y₁₂ inhibitor interruption after percutaneous coronary intervention before elective non-cardiac surgery. LoE, level of evidence; MI, myocardial infarction; N, no; PCI, percutaneous coronary intervention. Y, yes; ^aAvailability of 24 h cath-lab service is suggested in case of major surgery within 6 months in non-ACS/non-high-risk patients and within 12 months in ACS/high-risk patients. ^bHigh risk of peri-operative stent thrombosis defined by at least one of the following: history of recurrent MI, history of stent thrombosis under antiplatelet therapy, reduced left ventricular ejection fraction (<40%), poorly controlled diabetes, severely impaired renal function/haemodialysis, recent complex PCI (i.e. severely calcified lesion, left main PCI, chronic total occlusion, bifurcational/crush technique, bypass graft PCI), stent malapposition/residual dissection. ^cClass III LoE C. ^dClass IIa LoE B ^{250,265, 266,267}. ^eClass I LoE A ^{268,146}. ^fClass III LoE B ²⁶⁹. ^gClass IIb LoE B ^{270, 271}. ^hClass IIa LoE B ^{272,273,274, 275, 276,277,278}. ⁱClass I LoE A ^{279, 280, 281, 98}.

the management of acute coronary syndromes in patients presenting without persistent ST-segment elevation;⁹⁸ therefore, periprocedural management of clopidogrel-based single antiplatelet therapy (SAPT) is required. Consensus has been reached that a short interruption of P2Y₁₂ inhibitor monotherapy is recommended in patients at high risk of bleeding.

Patients treated with P2Y₁₂ inhibitor monotherapy as part of a de-escalation strategy after PCI/ACS, or due to a recent stroke, PAD, or aspirin intolerance, might require peri-operative management of this monotherapy.^{248–250} A careful interdisciplinary evaluation of peri-operative bleeding vs. ischaemic risk is warranted in these situations, and individual decisions based on the peri-operative bleeding and ischaemic risk (e.g. surgery under P2Y₁₂ monotherapy, switching to aspirin, short interruption, or bridging in the peri-operative phase) may be applicable, although evidence for these different regimens is

missing. It should be recognized that the effects of ticagrelor or clopidogrel monotherapy on haemostasis are considerably less than when they are combined with aspirin.

5.3.1.2. Dual antiplatelet therapy

P2Y₁₂ inhibitors in addition to aspirin are recommended for patients after PCI.^{98,146} The frequency of major NCS in the first year after PCI is ~4%; most frequently orthopaedic, abdominal, and vascular surgery.²⁵¹ Other observational data report cumulative incidences of NCS after PCI for 30 days, 6 months, and 1 year of 1%, 5%, and 9%, respectively.²⁵²

Observational studies have reported a substantial rate of MACE—including cardiac death, MI, and stent thrombosis—ranging between 2–8%^{251,253,254} in PCI patients undergoing NCS, with a more than two-fold increased risk compared with non-stented patients.^{255,256}

Figure 7 Bridging with intravenous antiplatelet agents. ASA, acetylsalicylic acid; FU, follow-up; LD, loading dose; NCS, non-cardiac surgery; o.d., once a day. ^aTirofiban: 0.1 µg/kg/min; if creatinine clearance <50 mL/min, adjust to 0.05 µg/kg/min. Eptifibatide: 2.0 µg/kg/min; if creatinine clearance is <50 mL/min, adjust to 1.0 µg/kg/min. ^bUntil oral P2Y₁₂ inhibitor therapy is possible. ^cInitiate within 72 h from P2Y₁₂ inhibitor discontinuation at a dose of 0.75 µg/kg/min for a minimum of 48 h and a maximum of 7 days.

The proportion of risk attributable to underlying CVD or stent implantation remains uncertain.²⁵⁴ Risk factors for MACE after NCS are: time from PCI to surgery, with the highest risk in the first month; primary PCI for ST-segment elevation myocardial infarction (STEMI); dual antiplatelet therapy (DAPT) interruptions/discontinuation; and lesion characteristics, including ostial and distal lesions.^{252,257–259} Urgency of surgery is a further risk factor. The ESC/ESA classification of NCS is a validated tool with which to predict the impact of the type of surgery on MACE.¹⁶

A meta-analysis of observational data indicated that discontinuation of clopidogrel for at least 5 days reduced the risk of reoperation for major bleeding by 50%, without increasing the risk of MACE or death.²⁶⁰ Other observational data indicate an increase in MACE with brief DAPT interruptions.²⁶¹ However, these non-randomized data may have been biased by the type and urgency of surgery.²⁶⁰ Of note, the prognosis of stent thrombosis appears to

be worse than for *de novo* coronary occlusion (and depends on the site of stent deployment), and premature interruption of DAPT in patients with recent coronary stent implantation is the strongest predictor for stent thrombosis.

The preferred management of patients on DAPT due to PCI is to delay elective NCS until completion of the full course of DAPT (6 months after elective PCI and 12 months after ACS).^{98,146} However, several recent trials have indicated that shortening DAPT duration to 1–3 months after implantation of modern DES is associated with acceptable rates of MACE and stent thrombosis in low- and moderate-risk patients. Based on these newer data, it is recommended to delay time-sensitive NCS until a minimum of 1 month of DAPT treatment has been effectuated. In high-risk CV patients, for example due to an ACS, a DAPT duration of at least 3 months should be considered before time-sensitive NCS. See Figure 5 for the recommended duration of DAPT before

time-sensitive NCS. Once the P2Y₁₂ inhibitor has been discontinued, surgery should be performed while the patient is still on aspirin.

Indications for long-term DAPT have recently emerged. Long-term DAPT (beyond 1 year) with clopidogrel, prasugrel, or ticagrelor in addition to aspirin should be considered in patients with high ischaemic risk, and may be considered in patients with moderate ischaemic risk, both in the absence of increased risk of major or life-threatening bleeding.⁹⁸ When NCS is required, discontinuation of P2Y₁₂ inhibitors is recommended for 3–7 days (depending on the P2Y₁₂ inhibitor) for these additional indications for DAPT.

5.3.1.3. De-escalation of antiplatelet effect

The management of antiplatelet therapy in patients who have undergone recent PCI and are scheduled for NCS should be discussed by the surgeon and cardiologist, so that the balance between the risk of life-threatening surgical bleeding on antiplatelet therapy—best understood by the surgeon—and the risk of life-threatening stent thrombosis due to premature DAPT discontinuation—best understood by the cardiologist—can be considered (Figure 5 and Figure 6). An increased risk of MACE as a consequence of (major) bleeding also needs to be taken into consideration when balancing risk.

When time-sensitive surgery cannot be postponed and be performed with the recommended DAPT on board, de-escalation or shortening of DAPT is recommended. This may encompass either a switch from the more potent P2Y₁₂ inhibitors prasugrel or ticagrelor to clopidogrel, or cessation of aspirin and use of prasugrel or ticagrelor monotherapy. If neither of these options is deemed to be sufficient, premature discontinuation of the P2Y₁₂ inhibitor may be considered. If discontinuation is required, ticagrelor needs to be withheld for 3–5 days, clopidogrel for 5 days, and prasugrel for 7 days prior to surgery.^{262–264}

Whenever possible, in patients with an indication for DAPT, surgery should be performed without discontinuation of aspirin. Aspirin might be discontinued as a last measure only with very high bleeding risk and a comparably low ischaemic risk. However, such surgical procedures should be performed in hospitals where 24/7 catheterization laboratories are available so as to treat patients immediately in case of peri-operative ischaemic events.

Although generally not recommended, bridging with i.v. compounds (eptifibatide/tirofiban or cangrelor) might be applicable in rare cases when DAPT cannot be interrupted before NCS (e.g. in patients with very high risk of stent thrombosis, history of recurrent MI, recent PCI) (see Figure 5 and Figure 7).²⁸²

For patients receiving antiplatelet therapy, who have excessive or life-threatening peri-operative bleeding, transfusion of platelets is recommended as a bail-out strategy. However, ticagrelor and its active metabolite may also inhibit aggregation of transfused platelets. Experimental data indicate that administration of albumin binds ticagrelor and reduces its inhibitory effect on platelet aggregation.²⁸³ A monoclonal antibody fragment (PB2452) for neutralizing ticagrelor is in development but is not yet clinically available.²⁸⁴

5.3.1.4. Platelet function guided peri-operative management of antiplatelet therapy

Platelet function testing has several theoretical advantages in the peri-operative setting, including: (i) the identification of patients on antiplatelet therapy who are at increased risk of surgery-related

bleeding; (ii) individualized timing of elective surgery after antiplatelet therapy cessation; and (iii) guiding therapy in bleeding complications.^{285–287} However, neither the optimal assay nor a universal cut-off value associated with bleeding has been defined and validated in patients undergoing NCS.

Recommendation Table 13 — Recommendations for use of antiplatelet therapy in patients undergoing non-cardiac surgery

Recommendations	Class ^a	Level ^b
It is recommended to delay elective NCS until 6 months after elective PCI and 12 months after an ACS. ^{264,271}	I	A
After elective PCI, it is recommended to delay time-sensitive NCS until a minimum of 1 month of DAPT treatment has been given. ^{266,271,288,289}	I	B
In patients with a recent PCI scheduled for NCS, it is recommended that management of antiplatelet therapy is discussed between the surgeon, anaesthesiologist, and cardiologist.	I	C
In high-risk patients with a recent PCI (e.g. STEMI patients or high-risk NSTEMI-ACS patients), a DAPT duration of at least 3 months should be considered before time-sensitive NCS.	IIa	C
Continuation of medication		
In patients with a previous PCI, it is recommended to continue aspirin peri-operatively if the bleeding risk allows. ²⁴⁴	I	B
Recommended time interval for drug interruption before NCS		
If interruption of P2Y ₁₂ inhibitor is indicated, it is recommended to withhold ticagrelor for 3–5 days, clopidogrel for 5 days, and prasugrel for 7 days prior to NCS. ^{262–264}	I	B
For patients undergoing high bleeding risk surgery (e.g. intracranial, spinal neurosurgery, or vitreoretinal eye surgery), it is recommended to interrupt aspirin for at least 7 days pre-operatively.	I	C
In patients without a history of PCI, interruption of aspirin at least 3 days before NCS may be considered if the bleeding risk outweighs the ischaemic risk, to reduce the risk of bleeding. ²⁴³	IIb	B
Resumption of medication		
If antiplatelet therapy has been interrupted before a surgical procedure, it is recommended to restart therapy as soon as possible (within 48 h) post-surgery, according to interdisciplinary risk assessment.	I	C

ACS, acute coronary syndrome; DAPT, dual antiplatelet therapy; NCS, non-cardiac surgery; NSTEMI-ACS, non-ST-segment elevation acute coronary syndrome; PCI, percutaneous coronary intervention; STEMI, ST-segment elevation myocardial infarction.

^aClass of recommendation.

^bLevel of evidence.

5.3.2. Oral anticoagulants

Approximately one in four patients taking anticoagulant therapy will require a surgical or invasive procedure within 2 years.²⁹⁰ Peri-operative management of oral anticoagulant (OAC) therapy depends on surgery- and patient-related factors and the specific OAC agent (vitamin K antagonist [VKA] or a non-vitamin K antagonist oral anticoagulant [NOAC]). See [Figure 8](#) for a summary of recommendations for the management of OACs in patients undergoing NCS.

Surgery-related factors include urgency of the intervention and the procedure-related bleeding risk (reflecting both the risk of bleeding occurrence and the risk of adverse outcome if bleeding occurs) (see [Table 8](#)). Procedures where mechanical compression is unfeasible carry a high risk of serious bleeding complications.

Patient-related factors include age, individual thrombotic risk, history of bleeding complications, renal function, concomitant

medication, comorbidity, etc. Patients requiring a reversal agent need careful monitoring of haemostatic parameters and evaluation of thrombotic and bleeding risk in the peri-operative phase, as reversal might be insufficient or prothrombotic rebound might occur. In the latter case, an interdisciplinary decision should be made with regard to early resumption of anticoagulation treatment.

5.3.2.1. Vitamin K antagonists

Three drugs are currently used: warfarin (half-life 36–48 h), acenocoumarol (half-life 12 h), and phenprocoumon (half-life 100 h).

5.3.2.1.1. Vitamin K antagonists in patients with mechanical heart valves. Maintenance of therapeutic international normalized ratio (INR) is crucial for patients with mechanical heart valves (MHVs).

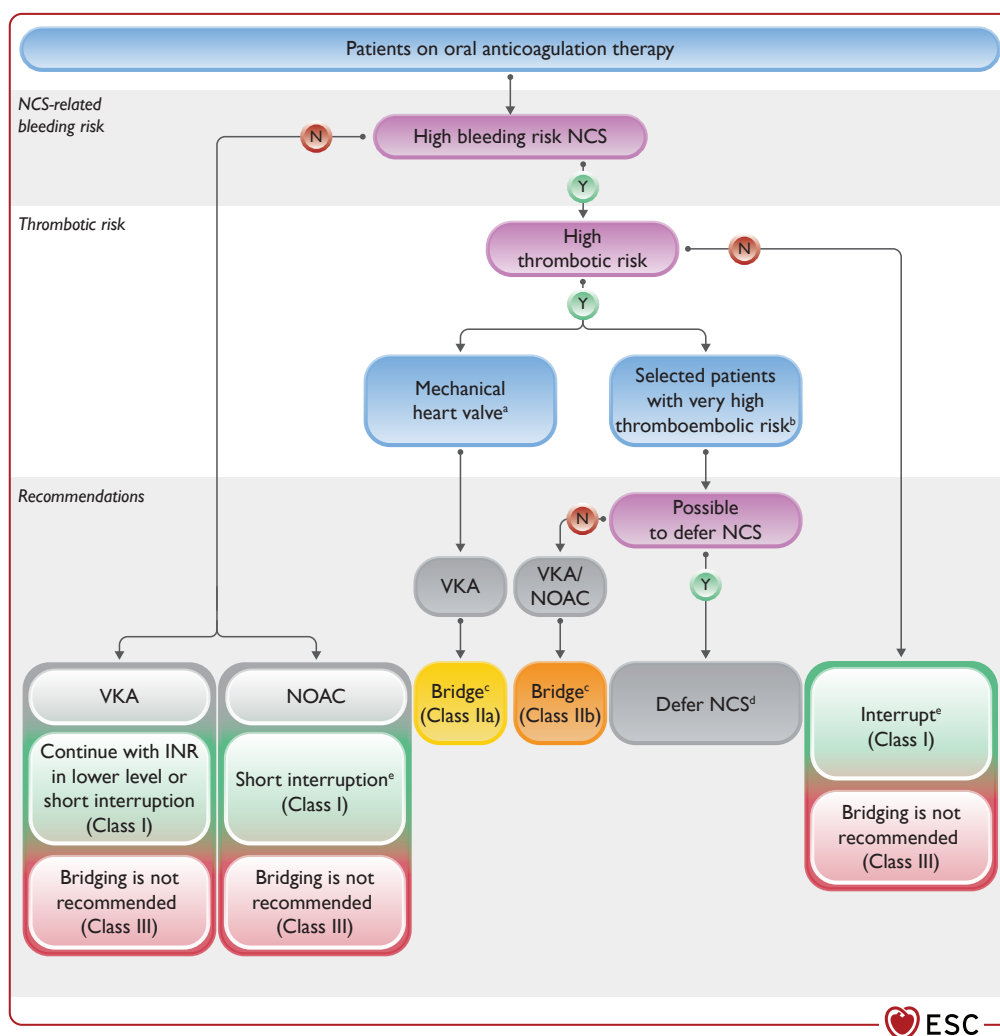

Figure 8 Recommendations for management of oral anticoagulation therapy in patients undergoing non-cardiac surgery. CHA₂DS₂-VAsC, congestive heart failure, hypertension, age ≥75 years, diabetes mellitus, stroke, vascular disease, age 65–74 years, sex category (female); N, no; NCS, non-cardiac surgery; NOAC, non-vitamin K antagonist oral anticoagulant; VKA, vitamin K antagonist; VTE, venous thromboembolism. Y, yes; ^aMechanical aortic valve replacement (AVR) and any thromboembolic risk factor (atrial fibrillation, previous thromboembolism, severe left ventricular dysfunction, hypercoagulable state), or older-generation mechanical AVR, or a mechanical mitral valve replacement. ^bRecent stroke <3 months, high risk of VTE recurrences (e.g. antithrombin 3 deficiency or protein C and/or S deficiency), left ventricular apex thrombus, atrial fibrillation with a very high stroke risk. ^cBridging with unfractionated heparin or low molecular weight heparin. ^dE.g. >3 months after stroke/VTE. ^eFor NOAC management during NCS, see [Figures 9 and 10](#).

Minor surgical procedures and procedures where bleeding is easily controlled can be performed without VKA interruption. The INR should be monitored and maintained at the lower level of the therapeutic range. Major surgical procedures needing INR ≤ 1.5 require VKA interruption, and heparin bridging should be considered. However, the evidence to support bridging therapy is limited and derived from cohort studies with poor or no comparator groups.²⁹¹ Furthermore, the current-generation mechanical prosthetic valves in the aortic position are associated with a lower risk of thromboembolism compared with the older ones.²⁹¹ Randomized controlled trials of bridging vs. no bridging therapy for patients with AF who do not have an MHV have shown higher risk of bleeding without a change in incidence of thromboembolic events, and increasing concerns have been raised that bridging therapy exposes patients to higher bleeding risks without reducing the risk of thromboembolism.^{292,293} The recently published PERI-OP trial compared bridging therapy vs. placebo in patients with either an MHV, AF, or atrial flutter who required interruption of OAC therapy for surgery, and found no significant benefit for post-operative dalteparin bridging to prevent major thromboembolism.²⁹⁴ The results were consistent for the AF ($n = 1166$) and MHVs groups ($n = 350$). Therefore, in patients with MHVs with a low risk of thromboembolism (e.g. mechanical bileaflet aortic valve in patients with sinus rhythm), bridging may not be needed. In patients with MHVs with a high risk of thromboembolism (mechanical aortic valve replacement [AVR] and any thromboembolic risk factor, or an older-generation mechanical AVR, or a mechanical mitral or tricuspid valve replacement), bridging with heparin should be considered during the peri-operative time interval when the INR is subtherapeutic (Figure 8). In all situations, the risks of bleeding should be weighed against the benefits of thromboembolism prevention.

Intravenous unfractionated heparin (UFH) is the only heparin treatment approved for bridging in patients with MHVs. Subcutaneous low molecular weight heparin (LMWH), although used off-label, has supplanted the use of UFH as a bridging therapy, owing to the lower incidence of thrombocytopenia, greater convenience, more predictable dose–response relationship, and significant cost saving resulting from outpatient administration. A meta-analysis of nine studies of 1042 patients with MHVs showed no differences between LMWH and UFH in the risks of thromboembolic events or major bleeding events.²⁹⁵ When LMWH is used, it should be given at a therapeutic dose twice a day and adjusted for renal impairment, when applicable. Anti-factor Xa (FXa) activity monitoring with target levels from 0.5–1.0 U/mL may be useful when the dosage may be difficult to determine (e.g. in patients with renal dysfunction or obesity). Vitamin K antagonist bridging strategies are shown in [Supplementary data, Figure S2](#).

5.3.2.1.2. Vitamin K antagonists for atrial fibrillation/venous thromboembolism. In patients using VKA for AF or venous thromboembolism (VTE), invasive procedures with a low bleeding risk can be performed without VKA interruption.^{296–299} The INR should be monitored and maintained at the lower level of the therapeutic range. When interruption is necessary due to high bleeding risk procedures, the BRIDGE trial in AF patients showed that 3–5 days of warfarin interruption without bridging was superior to heparin bridging, having the same incidence of arterial and venous thromboembolism and significantly lower incidence of major bleeding.²⁹²

Bridging therapy may be considered for patients with a high thrombotic risk (i.e. AF with CHA₂DS₂-VASc (congestive heart failure, hypertension, age ≥ 75 years, diabetes mellitus, stroke, vascular disease, age 65–74 years, sex category [female]) score >6 , recent cardioembolic stroke <3 months, or high risk of VTE recurrence, weighing the risk of bleeding against the risk of thromboembolism^{291,294,300} (see [Supplementary data, Figure S3](#)).

5.3.2.1.3. Restarting vitamin K antagonists after invasive procedures or surgery. Patients who have interrupted VKA treatment before surgery should restart the OAC 12–24 h after the invasive procedure, if the bleeding is well-controlled and gastric and intestinal reabsorption have been re-established. The restarting dose should be the maintenance dose plus a boosting dose of 50% for 2 days. Patients managed with bridging therapy should start LMWH or UFH together with VKA 24 h after surgery, if the bleeding is well-controlled and maintained, until the INR has reached the therapeutic range. In patients undergoing surgery with a high bleeding risk, therapeutic dose LMWH should be delayed for 48–72 h after haemostasis has been secured.

5.3.2.1.4. Reversal of vitamin K antagonists. Reversal of VKA can be managed with vitamin K, prothrombin complex concentrates (PPCs), and plasma administration. Vitamin K (from 2–10 mg depending on the INR value) can be used orally, with a predictable reduction in INR in 18–24 h or i.v. (in 25–50 mL normal saline over 15–30 min) for more rapid INR reduction (4–6 h). It should be noted that coagulation factors can still be below normal despite INR normalization, which means that bleeding risk might not yet be normalized. In patients needing reversal for immediate major surgery, PPCs or plasma should be used. Four-factor PPCs are the preferred option³⁰¹ and are dosed on the basis of INR and body weight (INR 2–4 at 25 U/kg, INR 4–6 at 35 U/kg, INR >6 at 50 U/kg, with a maximum dose of 5000 U at 100 kg of body weight). When four-factor PPCs are unavailable, three-factor PPCs or plasma may be used. Patients requiring a reversal agent need careful monitoring of haemostatic parameters and evaluation of thrombotic and bleeding risks in the peri-operative phase, as reversal might be insufficient or a prothrombotic rebound might occur. In the latter case, an interdisciplinary decision should be made with regard to early resumption of anticoagulation treatment.

5.3.2.2. Non-vitamin K antagonist oral anticoagulants

Four drugs are currently used: dabigatran (factor IIa inhibitor), apixaban, rivaroxaban, and edoxaban (FXa inhibitors). The pharmacokinetic and pharmacodynamic characteristics of these drugs are shown in [Table 8](#).

5.3.2.2.1. Unplanned surgery in patients on non-vitamin K antagonist oral anticoagulants and reversal for emergency procedures.

When an urgent surgical intervention is required, it is recommended that NOAC therapy is immediately interrupted. Peri-operative management of NOAC therapy in specific procedural settings and suggested strategies for potential reversal of NOAC anticoagulant effect are shown in [Figures 9–11](#)^{99,240,302} (see [Supplementary data, Table S5](#)).

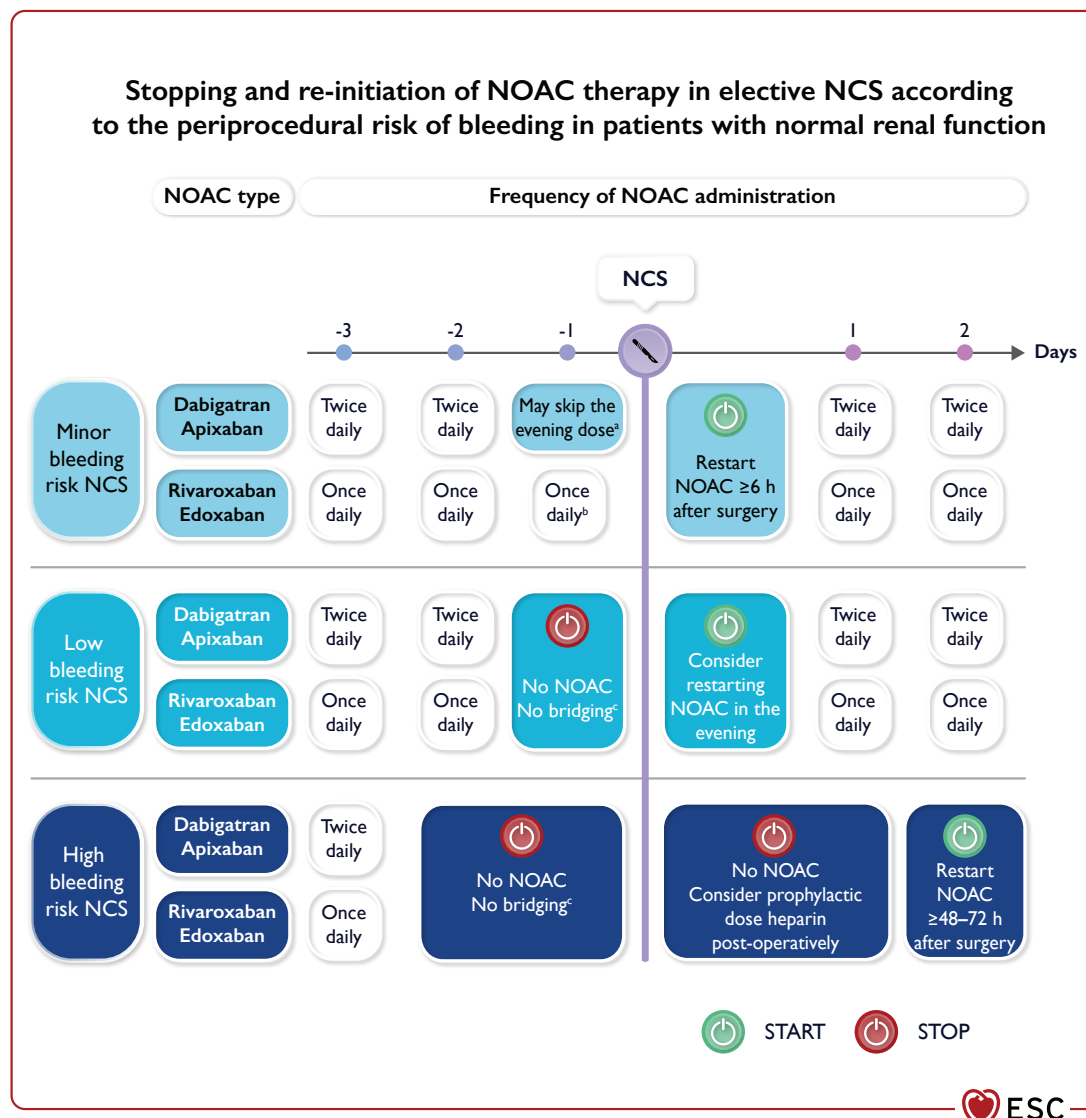

Figure 9 Peri-operative management of non-vitamin K antagonist oral anticoagulant according to the periprocedural risk of bleeding. NCS, non-cardiac surgery; NOAC, non-vitamin K antagonist oral anticoagulant. ^aIn patients/circumstances favouring NOAC accumulation (e.g. renal dysfunction, older age, concomitant medication), the NOAC should be paused 12–24 h earlier. ^bIn patients on rivaroxaban or edoxaban taking the dose in the evening, the evening dose may be skipped. ^cNOACs have predictable weaning of the anticoagulant effect. Owing to the increase in bleeding risk associated with bridging, it is generally not recommended to use bridging in patients taking NOACs. Very few circumstances when bridging with heparin may be considered in patients taking a NOAC include high thromboembolic risk conditions, such as: 1) patients with a recent (within 3 months) thromboembolic event (stroke, systemic embolism, or VTE); 2) patients who experienced a thromboembolic event during previous interruption of NOAC therapy.

Whereas the open-label prospective trial testing the specific reversal agent idarucizumab in patients on dabigatran enrolled participants experiencing acute major bleeding or requiring urgent surgical intervention,³⁰³ the trial with the reversal agent andexanet alpha for FXa inhibitors included only patients with acute major bleeding under therapy, but not those requiring urgent surgery.³⁰⁴ However, the off-label use of andexanet alpha in life-threatening situations requiring an immediate intervention may be considered, bearing in mind that andexanet alpha non-specifically binds all FXa inhibitors, which may have important implications for further treatment, including the administration of UFH or LMWH.²⁴⁰ When specific reversal

agents are unavailable, prothrombin complex concentrate (PCC) or activated PCC should be considered, although there is a lack of evidence on their efficacy and safety for emergency procedures in patients taking a NOAC.^{290,305} Performing immediate or urgent surgery under general rather than spinal anaesthesia is prudent, in order to reduce the risk of epidural haematoma.

Prior to unplanned surgery, the full panel of coagulation blood tests (see [Supplementary data, Table S6](#)) should be obtained in order to assess the patient's coagulation status. The indication for reversal (and/or non-specific haemostatic) agents is primarily governed by the patient's clinical presentation, but initial assessment of coagulation

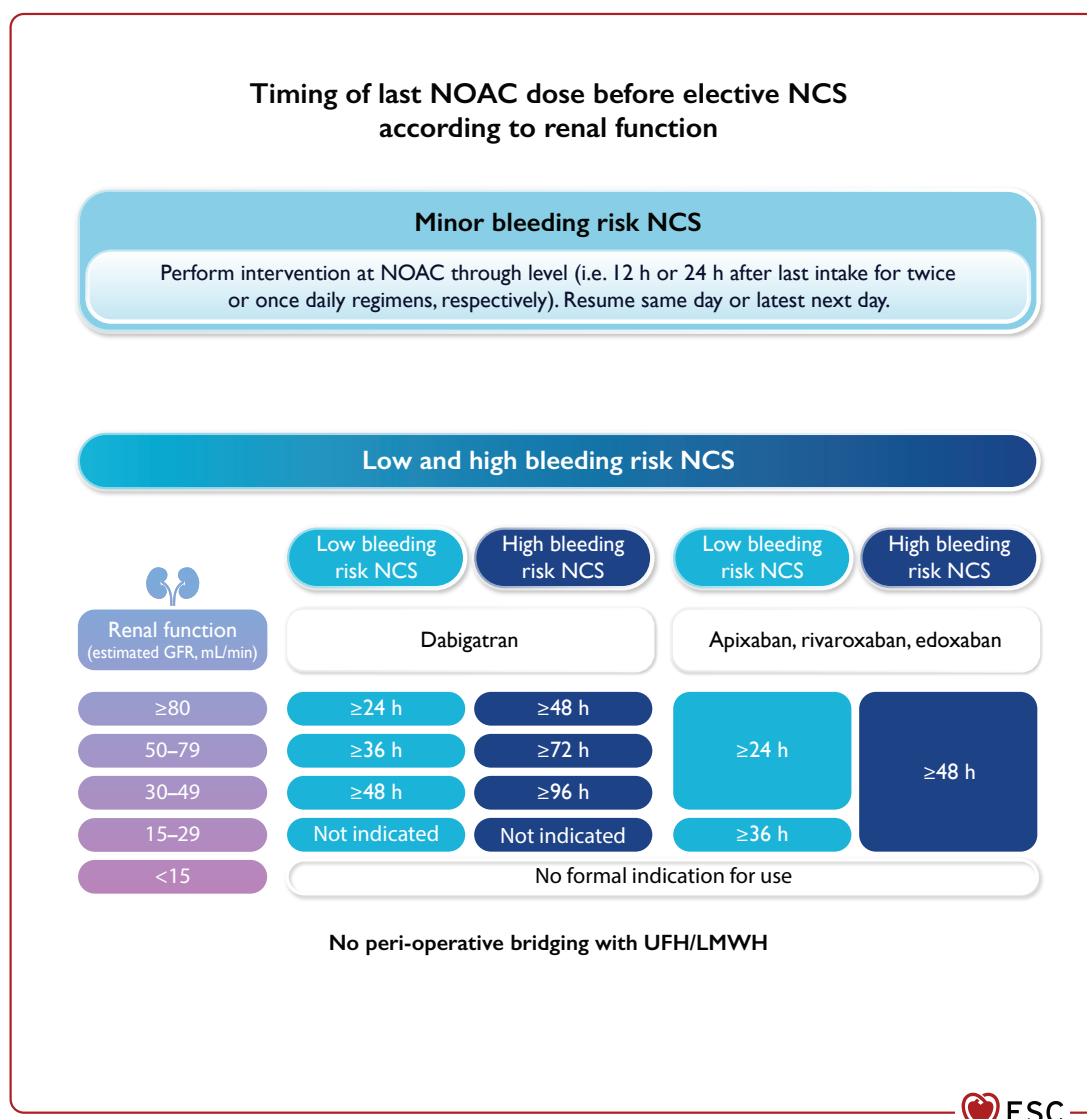

Figure 10 Timing of last non-vitamin K antagonist oral anticoagulant dose before elective NCS according to renal function. GFR, glomerular filtration rate; LMWH, low molecular weight heparin; NCS, non-cardiac surgery; NOAC, non-vitamin K antagonist oral anticoagulant; UFH, unfractionated heparin.

status may have important implications for treatment in the next few hours or days. Specific coagulation tests such as diluted thrombin time (dTT) or ecarin clotting assay for dabigatran and antiFXa chromogenic assays for FXa inhibitors, and the assessment of NOAC plasma levels, may help in interpreting routine coagulation tests and waning of anticoagulant effect.²⁴⁰

5.3.2.2.2. Planned interventions in patients on non-vitamin K oral anticoagulants. Invasive surgical interventions may require temporary discontinuation of NOAC therapy, while many less-invasive procedures with a relatively low risk of bleeding may be performed under minimally interrupted or uninterrupted NOAC therapy (Figure 9).²⁴⁰

5.3.2.2.3. Bridging. In patients taking a NOAC, peri-operative bridging using heparin or LMWH was associated with increased risk of bleeding without reduction in thromboembolic events.^{290,306–308} Therefore, when NOAC interruption is required for surgery, bridging

is not recommended, except in a few high thrombotic risk circumstances (see Figure 9). However, post-operative thromboprophylaxis with LMWH should be considered in patients in whom NOAC therapy cannot be quickly restarted. In patients receiving bridging with LMWH, monitoring of antiFXa activity and dose adjustment to a target level of 0.5–1.0 U/mL may be considered.

5.3.2.2.4. Laboratory testing before surgery. Pre-operative assessment of anticoagulation status in patients on a NOAC undergoing planned surgery provides a direct assessment of residual drug concentration. Shorter NOAC interruption time intervals in patients undergoing low-risk procedures may result in mildly or moderately elevated NOAC levels, as seen in the Perioperative Anticoagulant Use for Surgery Evaluation (PAUSE) trial,³⁰⁹ whereas creatinine clearance <50 mL/min, standard NOAC dose (compared with reduced dose), body weight <70 kg, and female sex were associated with elevated NOAC levels among patients undergoing high-risk surgery.

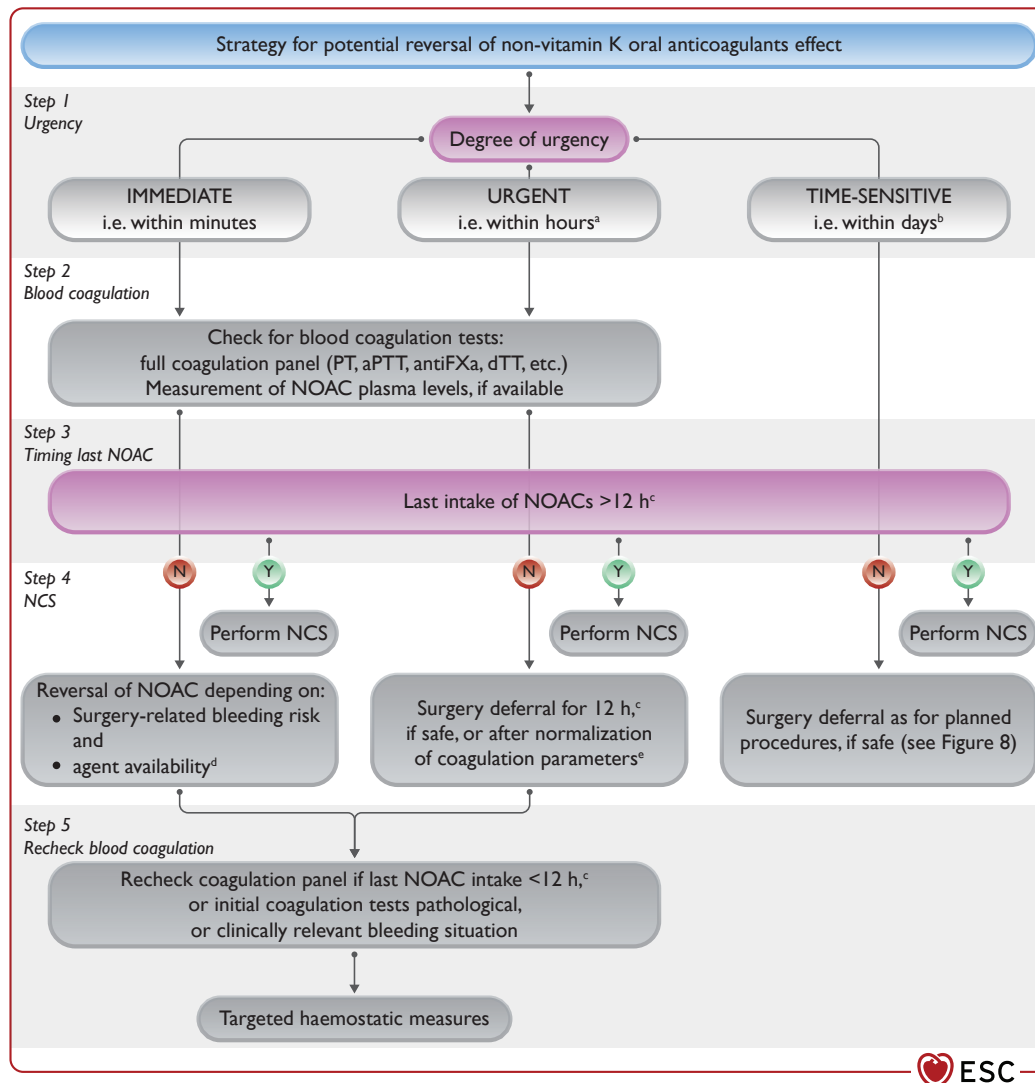

Figure 11 Suggested strategy for potential reversal of non-vitamin K oral anticoagulants effect. aPTT, activated partial thromboplastin time; dTT, diluted thrombin time; FXa, factor Xa; N, no; NOAC, non-vitamin K antagonist oral anticoagulant; PT, prothrombin time; UFH, unfractionated heparin. Y, yes; ^aConditions that are potentially life-threatening or that may threaten the survival of limb or organ. ^bConditions that can be managed and procedure delayed for several days. ^c>24 h in case of significantly reduced renal function (i.e. eGFR <50 mL/min). ^dIf specific reversal agent is unavailable, consider non-specific haemostatic agents (prothrombin complex concentrate [PCC] or activated PCC [aPCCs]). Idarucizumab has only been tested in patients undergoing urgent surgery. Andexanet has not been tested in patients requiring urgent surgery. Andexanet binds all FXa inhibitors (including UFH) non-specifically. ^eUpon re-check.

The use of amiodarone, verapamil, or diltiazem was also associated with elevated pre-operative NOAC levels in the prospective Per-procedural Concentration of Direct Oral Anticoagulants (CORIDA) trial.³¹⁰ Importantly, elevated NOAC levels were not found to be independently associated with bleeding complications.^{309,310}

The evidence base for modifying the duration of pre-operative NOAC interruption time intervals according to residual NOAC plasma levels is unavailable, and 'safe' plasma levels of NOACs for different procedures are largely unknown. The time-based NOAC interruption (Figure 9) appears safe in most patients undergoing surgery.^{311,312} When NOACs are interrupted for >72 h, the likelihood of any residual NOAC plasma levels is very low.^{309,310}

5.3.2.2.5. Considerations for specific procedures. Before interventions that carry a very high risk of bleeding—such as spinal or epidural anaesthesia, or lumbar puncture requiring intact haemostasis—interruption of NOACs for up to five half-lives (i.e. 3 days for FXa inhibitors or 4–5 days for dabigatran) should be considered, whereas NOACs can usually be restarted 24 h after the intervention.^{313,314}

Dental procedures are generally considered to be associated with minor bleeding risk, and adequate local haemostasis is usually easily achieved. Hence, most dental procedures can be performed in an outpatient setting, with uninterrupted NOAC (or a single skipped dose) and using specific local haemostatic measures (such as the application of oxidized cellulose or absorbable gelatine sponge, sutures,

tranexamic acid mouthwash or compressive gauze). Most professional statements on dental surgery advise uninterrupted NOAC, but these recommendations are mostly based on expert consensus, while some studies are currently ongoing.^{315–317}

5.3.2.2.6. When to restart non-vitamin K antagonist oral anticoagulants after interventions. In general, NOAC can be restarted 6–8 h after interventions with rapid and complete haemostasis. When the bleeding risk with full-dose anticoagulation resumption outweighs the risk of thromboembolic events, therapeutic anticoagulation may be postponed to >48–72 h after the procedure, using prophylactic post-operative thromboprophylaxis until the resumption of full-dose NOAC is deemed safe (Figure 9).²⁴⁰ Post-operative heparin administration should also be considered in patients unable to take oral therapy. Off-label use of reduced-dose NOACs to attenuate the risk of post-operative bleeding is not recommended, as there is no evidence informing such an approach.

5.3.2.3. Combination therapy (antiplatelet and anticoagulant)

In general, according to the 2020 ESC Guidelines for the diagnosis and management of atrial fibrillation developed in collaboration with the European Association for Cardio-Thoracic Surgery (EACTS), dual antithrombotic therapy should be adopted in most patients with AF and a recent PCI.⁹⁹ Elective surgery should be postponed until the period when antiplatelet therapy can be safely discontinued in combination therapy (6 months after elective PCI or 12 months after ACS).²⁶⁸ Peri-operative handling of NOACs should follow the above recommendations (Figures 9 and 10). In urgent/emergency surgery with high bleeding risk, operative measures to reduce bleeding and/or reversal strategies of anticoagulation might be applied. In patients receiving combination therapy for other indications (e.g. TAVI and AF), according to recent trial results, antiplatelet therapy can be safely discontinued before NCS.³¹⁸ In patients receiving low-dose OACs as part of a vascular protection strategy, rivaroxaban should be paused for at least 24 h before surgery and resumed according to the post-operative bleeding risk.

Recommendation Table 14 — Recommendations for interruption and resumption of anticoagulants in patients undergoing non-cardiac surgery

Recommendations	Class ^a	Level ^b
Interruption of anticoagulation		
When an urgent surgical intervention is required, it is recommended that NOAC therapy is immediately interrupted.	I	C
Idarucizumab should be considered in patients on dabigatran and requiring urgent surgical intervention with intermediate to high bleeding risk. ³⁰³	IIa	B

Continued

In non-minor bleeding risk procedures in patients using a NOAC, it is recommended to use an interruption regimen based on the NOAC compound, renal function, and bleeding risk. ^{310,311}	I	B
For interventions with a very high risk of bleeding, such as spinal or epidural anaesthesia, interruption of NOACs for up to five half-lives and re-initiation after 24 h should be considered.	IIa	C
When specific reversal agents are unavailable, PCC or activated PCC should be considered for reversing NOAC effects.	IIa	C
If an urgent surgical intervention is required, specific coagulation tests and assessment of NOAC plasma levels should be considered to interpret routine coagulation tests and waning of anticoagulant effect.	IIa	C
Continuation of medication		
In minor bleeding risk surgery and other procedures where bleeding can be easily controlled, it is recommended to perform surgery without interruption of OAC therapy. ^{240,296–299}	I	B
LMWH is recommended, as an alternative to UFH, for bridging in patients with MHVs and high surgical risk. ²⁹⁵	I	B
In patients using NOACs, it is recommended that minor bleeding risk procedures are performed at trough levels (typically 12–24 h after last intake).	I	C
For patients with mechanical prosthetic heart valves undergoing NCS, bridging with UFH or LMWH should be considered if OAC interruption is needed and patients have: (i) mechanical AVR and any thromboembolic risk factor; (ii) old-generation mechanical AVR; or (iii) mechanical mitral or tricuspid valve replacement.	IIa	C
Bridging of OAC therapy is not recommended in patients with low/moderate thrombotic risk undergoing NCS. ^{290,292,293,306–308,311}	III	B
Start/resumption of medication		
If bleeding risk with resumption of full-dose anticoagulation outweighs the risk of thromboembolic events, postponing therapeutic anticoagulation 48–72 h after the procedure may be considered, using post-operative thromboprophylaxis until resumption of full OAC dose is deemed safe.	IIb	C
Use of reduced-dose NOAC to attenuate the risk of post-operative bleeding is not recommended.	III	C

AVR, aortic valve replacement; OAC, oral anticoagulant; LMWH, low molecular weight heparin; MHV, mechanical heart valve; NCS, non-cardiac surgery; NOAC, non-vitamin K oral anticoagulant; PCC, prothrombin complex concentrate; UFH, unfractionated heparin.

^aClass of recommendation.

^bLevel of evidence.

5.4. Peri-operative thromboprophylaxis

Trends show that the case-fatality of peri-operative VTE has declined over the past few decades.^{319,320} Its causal relationship with preventable mortality has been challenged by a recent meta-analysis.³²¹ Thus, peri-operative VTE should be regarded as a marker of increased mortality risk rather than a causal factor. Careful pre-operative assessment is essential to identify patients with increased VTE risk who might benefit from peri-operative thromboprophylaxis. Procedure-related (e.g. type of surgery and likelihood of post-operative immobilization) and patient-related factors contribute to the risk of VTE. For non-orthopaedic surgical patients at low risk of VTE, mechanical methods of VTE prophylaxis (graduated compression stockings, intermittent pneumatic compression, or venous foot pump) rather than pharmacologic prophylaxis or no prophylaxis are recommended. Patients with CV disease (e.g. patients with recent MI or HF) have increased risk of peri-operative VTE.³²² The Caprini score has been developed for risk stratification,³²³ and validated in different surgical settings (see [Supplementary data, Table S7](#)).^{324–327}

Thromboprophylaxis should be considered for patients with moderate (i.e. 5–8 points) and high scores (i.e. ≥ 9 points). Thromboprophylaxis should be initiated during the hospital stay until 12 h before NCS and continued post-operatively based on individual risk assessment for bleeding. In most cases, thromboprophylaxis should be continued until the patient becomes fully mobilized or until hospital discharge (usually up to 10 days). Extended pharmacological VTE prophylaxis beyond discharge is not routinely recommended in most non-orthopaedic surgical patients. Although there are insufficient data regarding thromboprophylaxis after cancer surgery (particularly major abdominal and/or pelvic surgery for cancer), the consensus is to extend treatment duration with preferred use of LMWH for 3–4 weeks. Decisions on prophylaxis in populations for which the Caprini score has not been validated (such as orthopaedic surgery) should be based on individual and procedure-specific risk factors. Among those, a previous VTE is the strongest risk predictor (see [Supplementary data, Table S7](#)).³²⁸ For special situations and populations (e.g. neurosurgery, elderly, obese), please refer to available specific practice guidelines.^{329–332}

Large phase 3 and phase 4 studies comparing NOACs with LMWH have shown similar results regarding efficacy and safety after major orthopaedic surgery.³³³ The usual time period for thromboprophylaxis after total knee and hip arthroplasty was up to 14 days and 35 days in RCTs, respectively,^{334–339} but large-scale data suggest safety of foreshortening the duration restricted to the hospital stay after fast-track surgery.³⁴⁰ Recent practice guidelines and a meta-analysis suggest a rationale for the use of aspirin as thromboprophylaxis in modern elective total hip and knee arthroplasty.^{341,342} However, there is a need for more adequately powered clinical trials with appropriate end-points comparing aspirin with other pharmacological methods. Aspirin should not be used as the sole initial agent for VTE prophylaxis, but switching to aspirin following a short course (e.g. 5 days) of rivaroxaban may be suitable for selected low-risk patients.³⁴³ It is recommended to implement patient care programmes—including post-operative mobilization, electronic prophylaxis recommendations, and teaching sessions regarding daily use of thromboprophylaxis—as these have been shown to be beneficial in reducing the risk of post-operative VTE complications.³⁴⁴

Recommendation Table 15 — Recommendations for thromboprophylaxis

Recommendations	Class ^a	Level ^b
It is recommended that decisions about peri-operative thromboprophylaxis in NCS are based on individual and procedure-specific risk factors. ^{328,332}	I	A
If thromboprophylaxis is deemed necessary, it is recommended to choose the type and duration of thromboprophylaxis (LMWH, NOAC, or fondaparinux) according to type of NCS, duration of immobilization, and patient-related factors. ^{328,332}	I	A
In patients with a low bleeding risk, peri-operative thromboprophylaxis should be considered for a duration of up to 14 or 35 days, for total knee or hip arthroplasty, respectively. ^{334–337}	IIa	A
NOACs in thromboprophylaxis dose may be considered as alternative treatments to LMWH after total knee and hip arthroplasty. ³³³	IIb	A

LMWH, low molecular weight heparin; NCS, non-cardiac surgery; NOAC, non-vitamin K oral anticoagulant.

5.5. Patient blood management

Major surgery is associated with a high risk of peri-operative blood loss. Preferred treatment of acute anaemia related to peri-operative blood loss is transfusion of allogenic blood products. However, a large body of evidence indicates that inappropriate transfusion of red blood cells (RBCs) may be associated with inherent complications and impaired surgical outcome. Therefore, it is important to identify at-risk patients pre-operatively and manage peri-operative bleeding in any patients undergoing major surgery.

A hallmark study including >200 000 major surgical patients showed that even mild anaemia significantly increased the risk of morbidity—including respiratory, urinary, wound, septic, and thromboembolic complications—and mortality across all age groups.³⁴⁵ Moreover, Baron and colleagues analysed >39 000 surgical patients and showed that anaemia was significantly associated with increased mortality rate, hospital length of stay, and post-operative admission to intensive care.³⁴⁶ Up to 48% of surgical patients suffer from anaemia, and therefore anaemia should be considered to be a risk factor any time during hospitalization.³⁴⁷ Von Heymann and colleagues analysed 4494 cardiac surgical patients and showed that pre-operative anaemia and intra-operative transfusion were independently associated with decreased long-term survival.³⁴⁸ In addition, long-term survival was decreased by 50% in anaemic patients receiving blood transfusion compared with those without blood transfusion.

Anaemia may contribute to myocardial ischaemia, particularly if CAD is present. Iron deficiency (ID) is the underlying cause of anaemia in ~50% of all cases.³⁴⁷ It was recently shown that ID was associated with increased risk of 90 day mortality both in patients with (4–14%) and without (2–5%) anaemia.³⁴⁹ In addition, the incidence

of serious adverse events, major cardiac and cerebrovascular events, allogenic blood transfusion requirements, and length of stay were increased in patients with ID.

Based on the possibility of preserving the patients' own blood resources and to enable safe handling of donor blood, the World Health Assembly (WHA) has endorsed the Patient Blood Management (PBM) approach (WHA63.12). Patient Blood Management is a patient-centred and multidisciplinary approach to manage anaemia, minimize iatrogenic blood loss and bleeding, and harness tolerance to anaemia in an effort to improve patient outcome.^{350–355} A comprehensive PBM programme addressing all three PBM pillars was associated with reduced transfusion need of RBC units, and lower complication and mortality rates.³⁵⁰

5.5.1. Pre-operative anaemia—diagnosis and treatment

A serum ferritin level <30 ng/mL, transferrin saturation <20%, and/or microcytic hypochromic red cells (mean corpuscular volume <80 fL, mean corpuscular haemoglobin <27 g/dL) are indicative of ID. In the presence of inflammation or transferrin saturation <20%, a ferritin level of <100 ng/mL points to functional ID (iron sequestration) (Table 10).

Apart from compromised bone marrow function, most types of anaemia are correctable within a period of 2–4 weeks. Oral and i.v. iron therapy can be used to treat ID. Intravenous iron products consist of an iron core embedded in a carbohydrate shell, which influences the stability of the drug, for example: iron sucrose comprises a less stable shell, allowing a maximum dose of 200 mg per infusion, whereas ferric carboxymaltose, ferric derisomaltose, and ferumoxytol have a stable shell associated with slow iron release and allowing a higher dose. Administration of i.v. iron has been shown to effectively reverse anaemia in ID patients.^{356,357}

Intravenous iron is efficacious and safe³⁵⁹ and should be used in patients in whom oral iron is not tolerated, or if surgery is planned in short notice after the diagnosis of ID. A prospective observational study of 1728 major surgical patients showed that the prevalence of ID was 50%, 46.3%, and 52.7% in patients with haemoglobin <8.0, 8.0–8.9, and 9.0–9.9 g/dL, respectively.³⁵⁷ Furthermore, all iron supplemented iron-deficient anaemic patients required fewer RBC transfusions during the post-operative period, and a reduced intra-operative transfusion rate was observed if iron was supplemented >7 days before surgery. In addition, the length of stay was

significantly reduced by 2.8 days for iron supplemented patients. In the recent PREVENTT trial studying patients with anaemia undergoing major abdominal surgery, pre-operative iron transfusion failed to improve outcomes;³⁶⁰ however, due to a fault in the study design, all anaemic patients received i.v. iron but not all (~50–70%) were suffering from ID.

Recombinant human erythropoietin (rHuEPO) has frequently been used together with iron supplementation to increase pre-operative haemoglobin concentrations. A recent Cochrane review found that the administration of rHuEPO + iron to anaemic patients prior to NCS, compared with control treatment, reduced the need for RBC transfusion and increased the haemoglobin concentration pre-operatively; however, there were no important differences in the risk of adverse events or mortality within 30 days, or in length of hospital stay.³⁶¹ Well-designed, adequately powered RCTs are required to more precisely estimate the impact of this combined treatment.

Pre-operative management of patients with anaemia can be simplified by making use of standard operating procedures or algorithms in which thresholds for diagnosis and treatment are depicted.³⁶² An example of such an algorithm can be found in the PBM programme³⁶³ (see Supplementary data, Figure S4) and in the British Committee for Standards in Haematology (BCSH) Guidelines on the Identification and Management of Pre-Operative Anaemia.³⁶⁴

Recommendation Table 16 — Recommendations for intra- and post-operative complications associated with anaemia

Recommendations	Class ^a	Level ^b
It is recommended to measure haemoglobin pre-operatively in patients scheduled for intermediate- to high-risk NCS. ^{350,354}	I	B
It is recommended to treat anaemia in advance of NCS, in order to reduce the need for RBC transfusion during NCS. ^{357,361}	I	A
The use of an algorithm to diagnose and treat anaemic patients before NCS should be considered.	IIa	C

NCS, non-cardiac surgery; RBC, red blood cell.

Table 10 Laboratory parameters for the diagnosis of absolute iron-deficiency anaemia

Parameter	Normal	Iron deficiency
Mean corpuscular haemoglobin (g/dL)	28–33	<27
Mean cellular volume (fL)	80–96	<80
Transferrin saturation (%)	16–45	<20
Ferritin (ng/mL)	18–360	<30 ^a
Reticulocytes haemoglobin (ng/mL)	18–360	<30

^aIn cases of chronic kidney disease, chronic heart failure or infections, iron deficiency is diagnosed with ferritin level <100 ng/mL or transferrin saturation <20%.³⁵⁸

5.5.2. Bleeding and reduction of iatrogenic diagnostic/surgery-related blood loss

Blood loss associated with laboratory testing can either cause or aggravate hospital-acquired anaemia, which is associated with increased length of stay and complications. In 1867 patients undergoing cardiac surgery, an average of 115 tests per patient were performed, with a cumulative median volume of 454 mL.³⁶⁵ A reduction in blood drawn for laboratory analyses can be achieved by lowering the frequency of sampling and using paediatric-size collection tube sizes, for example. To decrease blood loss, blood-saving bundles could be used (e.g. a closed-loop arterial blood sampling system, smaller sampling tubes, reduction of frequency of blood

drawings, and sample numbers). Such a strategy decreased mean blood loss per intensive care unit (ICU) day from 43.3 mL to 15.0 mL ($P < 0.001$),³⁶⁶ mainly due to the introduction of closed-loop arterial blood sampling systems. In addition, units of transfused RBCs per 100 observation days decreased from 7 to 2.3 ($P < 0.001$).³⁶⁶

A reduction in surgery-related blood loss starts from the pre-operative stage, with appropriate cessation strategies for anticoagulation and antiplatelet therapy. Intra-operative approaches to avoid blood loss include: (i) advanced anaesthetic; (ii) advanced surgical techniques with meticulous haemostasis, such as minimally invasive surgery and laparoscopic surgery; (iii) judicious use of diathermy dissection; (iv) physician's mindfulness regarding limiting blood loss; and (v) application of topical haemostatic agents.^{367–369}

Adequate coagulation management to minimize blood loss needs to be a pre-condition before RBC transfusion is considered. In this respect, the use of a coagulation algorithm is recommended,^{370,371} encompassing pre-operative assessment,³⁷² and ensuring basic conditions for haemostasis, reversal of anticoagulants, point-of-care diagnostics in bleeding patients, and optimized coagulation management with the use of clotting factor concentrates.^{373,374}

Tranexamic acid is an antifibrinolytic agent that is widely used for prophylaxis and treatment of bleeding caused by hyperfibrinolysis. A meta-analysis including 129 trials encompassing more than 10 000 patients to assess the effect of tranexamic acid on blood transfusion showed that administration of tranexamic acid reduced allogeneic blood transfusion by 38% ($P < 0.001$).³⁷⁵ In the recent POISE-3 study, 9535 patients undergoing NCS were randomized to tranexamic acid (1 g i.v. bolus) or placebo at the start and end of surgery. The incidence of the primary efficacy outcome (composite bleeding outcome) at 30 days was significantly lower with tranexamic acid than with placebo (HR, 0.76; 95% CI, 0.67–0.87).³⁷⁶ With respect to the primary safety outcome (composite CV outcome), the results did not meet the non-inferiority criteria (HR, 1.02; 95% CI, 0.92–1.14; $P = 0.04$ for non-inferiority).

The use of (washed) cell recovery is highly recommended in surgical settings where blood loss is routinely or anticipated to be >500 mL, as it reduces the rate of exposure to allogeneic RBCs, risk of infection, and length of stay. A meta-analysis including 47 trials encompassing 3433 patients of all surgical disciplines showed that the use of washed cell salvage reduced the rate of exposure to allogeneic RBC transfusion by 39% ($P < 0.001$), risk of infection by 28% ($P = 0.03$), and length of stay by 2.31 days ($P < 0.001$).³⁷⁷

Recommendation Table 17 — Recommendations for intra- and post-operative complications associated with blood loss

Recommendations	Class ^a	Level ^b
In patients undergoing surgery with expected blood loss of ≥ 500 mL, use of washed cell salvage is recommended. ^{377,378}	I	A
It is recommended to use point-of-care diagnostics for guidance of blood component therapy, when available. ^{370,379–383}	I	A

Continued

In patients undergoing NCS and experiencing major bleeding, administration of tranexamic acid should be immediately considered. ^{375,376,384–386}	IIa	A
Use of closed-loop arterial blood sampling systems should be considered to avoid blood loss. ^{366,378,387,388}	IIa	B
Application of meticulous haemostasis should be considered a routine procedure. ^{350,389}	IIa	B

NCS, non-cardiac surgery.

5.5.3. Optimal blood component use with patient-centred clinical decision support

In order to optimize utilization of allogeneic blood products and to ensure guideline-adherent transfusion strategies, computerized physician order-entry systems should be considered.^{390,391} For example, Kaserer and colleagues evaluated the effectiveness of a monitoring and feedback programme and compared transfusion rates of >210 000 patients before and after implementation;³⁹² overall, transfusion of RBCs was reduced by 40%.

Informed consent should be obtained from patients prior to transfusion of allogeneic blood products. It is necessary to effectively communicate the risks and benefits of the various potential interventions to the patient. It may further be recommended that any transfusion of allogeneic blood products should be mentioned in the discharge summary. In addition, the patient's own preferences and values should be considered when developing a medical plan.

Recommendation Table 18 — Recommendations for intra- and post-operative complications associated with allogeneic blood transfusion

Recommendations	Class ^a	Level ^b
A feedback/monitoring programme or clinical decision support system should be considered to be assessed before blood transfusion. ^{392–396}	IIa	B
Before allogeneic blood transfusion, it should be considered to obtain an extensive consent about risks associated with transfusion.	IIa	C

6. Specific diseases

Patients with CVD have an increased risk of peri-operative CV complications.⁴⁵ Both the risk of complications and the peri-operative management depend on the specific type of CVD.

6.1. Coronary artery disease

6.1.1. Risk for patients with coronary artery disease

The peri-operative risk of CV complications for patients with established CAD depends on the baseline CV risk, type of surgery, and

degree of urgency of the NCS. Older patients have a higher risk than younger patients, and patients with a recent ACS have a higher risk than those with CCS. The presence of comorbidities may also influence the risk.

6.1.2. Pre-operative risk assessment and management

The diagnostic evaluation and pre-operative management of patients with CCS undergoing NCS are outlined in [Section 4](#). In particular, the value of CCTA and ICA are discussed in [Sections 4.5.3.1. and 4.5.3.2.](#)

In patients in need of immediate NCS, the operation must be performed without further delay and the time for pre-operative assessment is limited.

In patients scheduled for elective NCS who present with an ACS, the management of ACS should follow the guidelines for ACS patients in the non-surgical setting.^{98,171} In such settings, it would be reasonable to consider treating the culprit lesion only before NCS. Potential changes in timing of surgery and the peri-operative management (e.g. type of surgery, anaesthesia, medical therapy, and peri-operative monitoring) should be considered.

In patients with known CAD, it is recommended to collect information regarding previous invasive and non-invasive diagnostic examinations, and therapeutic interventions for CAD, within a sufficient time interval before the NCS, ideally at the time the proposal for NCS is made.

6.1.3. Revascularization strategies

The indication for coronary revascularization depends on the clinical presentation of CAD (ACS vs. CCS), urgency, and cardiac risk of NCS. In general, there is clear evidence that routine revascularization improves outcomes in ACS patients and less support for such a strategy in patients with CCS. The process of decision-making related to revascularization in CCS should be individualized, in order to prioritize revascularization in case of involvement of a significant amount of ischaemic myocardium or refractory symptoms, while medical management is a valuable option in patients with less relevant CAD manifestations.

6.1.3.1. Chronic coronary syndromes

The rationale for coronary revascularization before NCS is to prevent peri-operative myocardial ischaemia leading to acute MI, haemodynamic instability, and arrhythmia. Data from autopsy studies following fatal peri-operative MI showed that more than two-thirds of the patients had significant left main or three-vessel disease.³⁹⁷ A retrospective registry based on the Coronary Artery Surgery Study (CASS) study found that coronary artery bypass graft (CABG) reduced the risk of peri-operative mortality and MI in patients undergoing major NCS, particularly in subjects with three-vessel disease and reduced left ventricular ejection fraction (LVEF).³⁹⁸ However, the evidence in support of routine prophylactic revascularization before NCS is based on relatively small clinical trials and retrospective registries unrepresentative of current clinical practice.

In the Coronary Artery Revascularization Prophylaxis (CARP) trial, 510 patients with CCS were randomized to either optimal medical therapy or coronary revascularization (surgical or percutaneous) before major vascular surgery.³⁹⁹ In this study, patients receiving coronary revascularization compared with those who were medically

treated did not differ in terms of acute MI after 30 days (8.4% vs. 8.4%, respectively) and mortality after 2.7 years (22% vs. 23%, respectively). Of note, this study excluded patients with significant left main disease, while one-third of the patients presented with three-vessel disease.³⁹⁹ In another randomized trial, 426 patients without evidence of CAD and scheduled for CEA were randomized to either routine coronary angiography with provisional revascularization before CEA or CEA without previous coronary angiography. There were no significant differences between the treatment groups in all-cause mortality, acute MI, and stroke at 30 days.¹⁷² A subsequent meta-analysis including 3949 patients showed no clinical benefit associated with routine prophylactic revascularization before NCS.⁴⁰⁰ A recent retrospective analysis on 4414 patients undergoing total joint arthroplasty found that the risk of adverse CV events was increased in patients with CAD, regardless of coronary revascularization before surgery. However, in patients receiving coronary revascularization, the risk of adverse CV events decreased, as the interval between revascularization and total joint arthroplasty was >2 years.⁴⁰¹

The lack of evidence in support of routine prophylactic revascularization in CCS does not preclude a decision-process based on individual risk–benefit assessment in patients with a significant amount of ischaemic myocardium (as in the case of left main disease) and/or with refractory symptoms. The International Study of Comparative Health Effectiveness with Medical and Invasive Approaches (ISCHEMIA) trial randomized 5179 patients with stable CAD and moderate or severe ischaemia to an initial invasive strategy (consisting of angiography plus revascularization, as appropriate) or to an initial strategy of medical therapy alone, with bail-out angiography if medical therapy failed.⁴⁰² This trial did not find a significant difference in the primary composite end-point of death and MI between treatment groups. Interestingly, these neutral results were inapplicable to patients with severe left main disease, since these patients were excluded after a pre-randomization CCTA. It has yet to be demonstrated whether CCTA represents a valuable tool with which to select patients with stable CAD and/or moderate or severe ischaemia who might benefit from an initial invasive strategy. A large angiography-based registry of 9016 CCS patients with high-risk coronary anatomy (three-vessel disease with $\geq 70\%$ stenosis in all three epicardial vessels or left main disease $\geq 50\%$ stenosis) showed improved outcomes (all-cause mortality or MI) in patients undergoing revascularization (both for PCI or CABG) vs. conservative medical therapy (HR, 0.62; 95% CI, 0.58–0.66; $P < 0.001$).⁴⁰³

The 2018 ESC/EACTS Guidelines on myocardial revascularization and the 2019 ESC Guidelines for the diagnosis and management of chronic coronary syndromes generally apply to this population of patients, as long as the NCS can be postponed long enough to allow safe discontinuation of DAPT.^{146,404} Similarly, the choice between PCI and CABG should follow the general rules outlined in the above-mentioned guidelines.^{268,404} The use of intravascular imaging for planning and optimization of PCI is encouraged.^{405,406}

6.1.3.2. Acute coronary syndromes

There are no trials specifically addressing the strategy of revascularization in ACS patients scheduled for NCS. High- and very high-risk

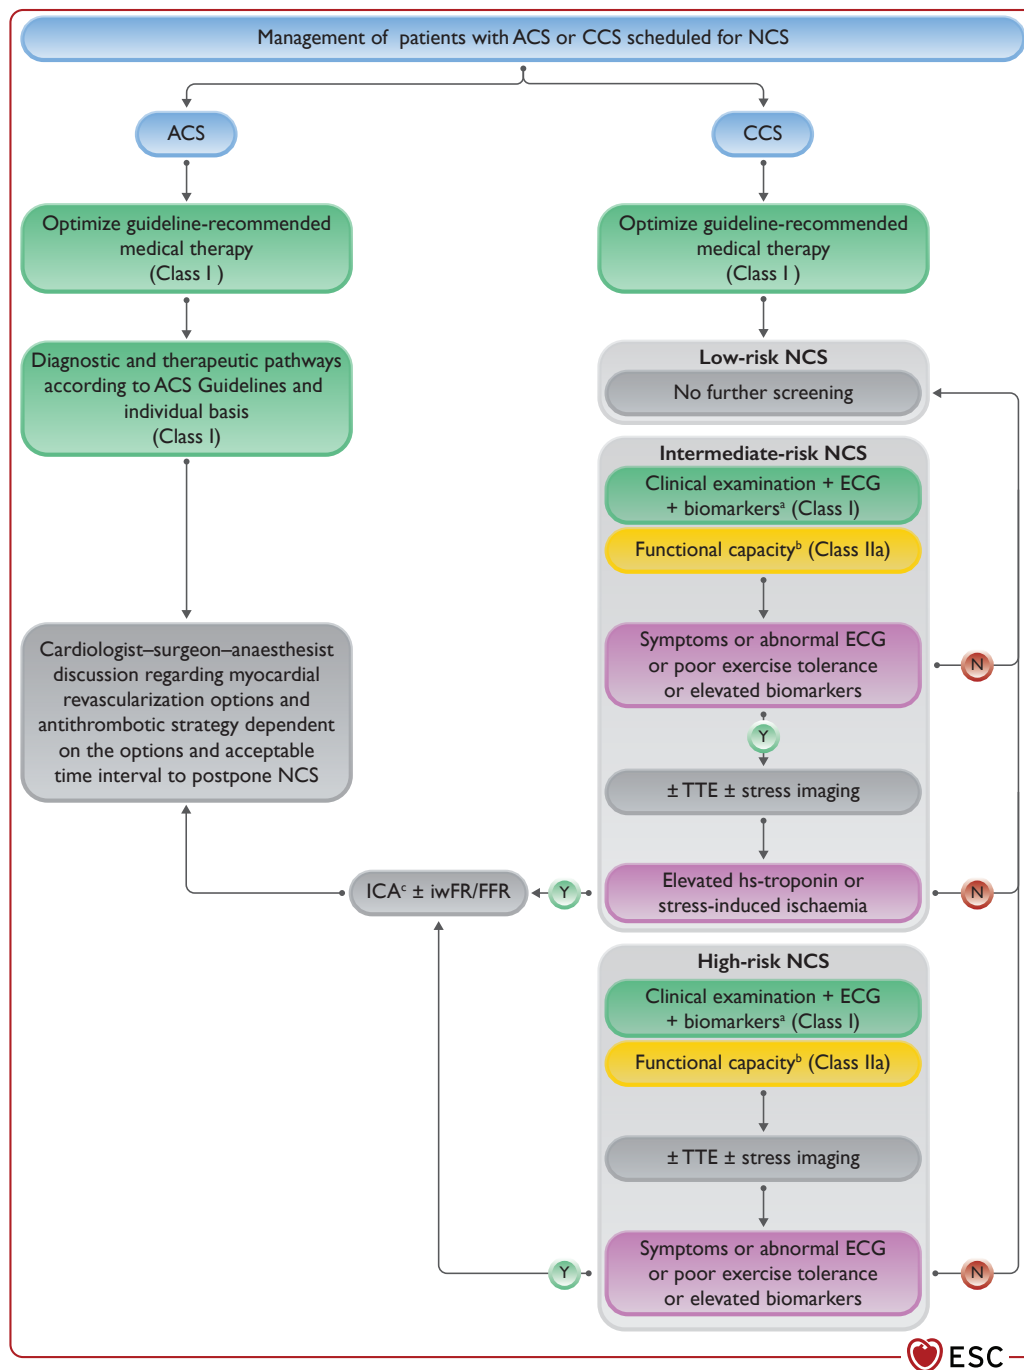

Figure 12 Management of patients with acute or chronic coronary syndrome scheduled for non-cardiac surgery. ACS, acute coronary syndrome; BNP, B-type natriuretic peptide; CABG, coronary artery bypass graft; CAD, coronary artery disease; CCS, chronic coronary syndrome; ECG, electrocardiogram; FFR, fractional flow reserve; hs-cTn, high-sensitivity cardiac troponin; ICA, invasive coronary angiography; iwFR, instantaneous wave-free ratio; N, no; NCS, non-cardiac surgery; NT-proBNP, N-terminal proBNP; PCI, percutaneous coronary intervention; TTE, transthoracic echocardiography. Y, yes; The figure provides a schematic representation of diagnostic tools and therapy to be implemented according to surgical risk and underlying cardiac condition. ^aBiomarkers: hs-cTn T/I (Class I) ± BNP/NT-proBNP (Class IIa). ^bFunctional capacity based on Duke Activity Status Index (DASI) or the ability to climb two flights of stairs. ^cICA ± PCI/CABG on a case-by-case basis according to the Heart Team.

patients should be treated according to the 2020 ESC Guidelines for the management of acute coronary syndromes in patients presenting without persistent ST-segment elevation,⁹⁸ with an early (<24 h) or immediate (<2 h) invasive strategy, respectively. In low-risk groups

amenable to a selective invasive strategy, the decision-making should be consistent with the approach for CCS patients.

In a post hoc analyses of the HIP-ATTACK (HIP Fracture Accelerated Surgical Treatment And Care track) trial, patients

with increased baseline troponin before randomization showed lower risk of mortality with accelerated surgery (within 6 h from the diagnosis) vs. standard of care (HR, 0.38; 95% CI, 0.21–0.66).⁵⁷

The selection of the type of revascularization (PCI or CABG) should be based on the coronary anatomy and complexity of atherosclerosis, and the presence of diabetes.^{268,404} When PCI is chosen, the use of a DES is recommended.⁴⁰⁷ In case of a life-threatening clinical condition requiring undeferrable NCS and concomitant ACS-STEMI with an indication for coronary revascularization, a minimalistic approach with plain balloon angioplasty and delayed stenting might be considered.^{408,409} Figure 12 shows a summary of diagnostic and therapeutic pathways in patients with CAD scheduled for NCS.

Recommendation Table 19 — Recommendations for the timing of non-cardiac surgery and revascularization in patients with known coronary artery disease

Recommendations	Class ^a	Level ^b
Patients with CCS		
If PCI is indicated before NCS, the use of new-generation DES is recommended over BMS and balloon angioplasty. ²⁶⁸	I	A
Pre-operative evaluation of patients with an indication for PCI by an expert team (surgeon and cardiologist) should be considered before elective NCS.	IIa	C
Myocardial revascularization before high-risk elective NCS may be considered, depending on the amount of ischaemic myocardium, refractory symptoms, and findings at coronary angiography (as in the case of left main disease). ^{399,402,403}	IIb	B
Routine myocardial revascularization before low- and intermediate-risk NCS in patients with CCS is not recommended. ^{399,400}	III	B
Patients with ACS		
If NCS can safely be postponed (e.g. at least 3 months), it is recommended that patients with ACS being scheduled for NCS undergo diagnostic and therapeutic interventions as recommended for ACS patients in general. ^{98,268}	I	A
In the unlikely combination of a life-threatening clinical condition requiring urgent NCS, and NSTEMI-ACS with an indication for revascularization, the priorities for surgery on a case-by-case basis should be considered by the expert team. ²⁶⁸	IIa	C

ACS, acute coronary syndrome; BMS, bare metal stent; CAD, coronary artery disease; CCS, chronic coronary syndrome; DES, drug-eluting stent; NCS, non-cardiac surgery; NSTEMI-ACS, non-ST-segment elevation acute coronary syndrome; PCI, percutaneous coronary intervention.

^aClass of recommendation.

^bLevel of evidence.

6.2. Chronic heart failure

6.2.1. Risk for patients with heart failure

Heart failure is an established risk factor for post-operative mortality across a broad range of surgical specialties.^{410–412} Several tools for risk calculations in patients undergoing NCS include HF as a predictor of adverse post-operative events.^{411,413}

The risk of adverse post-operative events associated with HF depends on whether the LV systolic function is preserved or reduced, on the haemodynamic compensation, and on the presence of symptoms.^{414,415} In patients undergoing NCS, there is a risk of acute decompensated HF, with rapid onset or worsening of symptoms and/or signs of HF, precipitated by fluid accumulation and/or comorbid conditions.⁴¹²

Patients with peri-operative acute or chronic HF are at increased risk of mortality during NCS. In a recently published analysis of 21 560 996 hospitalizations for NCS, the presence of any diagnosis of HF was associated with significantly higher in-hospital all-cause mortality compared with absence of HF (4.8% vs. 0.78%; adjusted OR, 2.15; 95% CI, 2.09–2.22).⁴¹⁶ Among patients with a chronic HF diagnosis, peri-operative mortality was greater in those with acute exacerbation of chronic HF compared to those with compensated chronic HF. In a recent large-scale cohort study of individuals undergoing ambulatory surgery, the crude 90 day mortality was 2.0% among patients with HF and 0.4% among patients without HF.⁴¹⁷ The crude risk of 30 day post-operative complications was 5.7% and 2.7%, respectively. Of note, the risk of mortality progressively increased with decreasing systolic function. It is not recommended to perform elective NCS in patients with decompensated HF.

The value of pre-operative assessment of LV function with TTE and measurement of natriuretic peptides (BNP or NT-proBNP) is discussed in Section 4.4. The TTE should not be older than 6 months, or performed just before NCS in the case of clinical worsening.

6.2.2. Pre- and post-operative management strategies

In order to reduce the risk of acute decompensation and the risk of mortality, optimal guideline-directed medical treatment of HF before scheduled NCS is recommended.⁴¹² Special attention should be given to the fluid balance, since high-volume infusion is often needed in the peri-operative period. Invasive monitoring of the arterial pressure aiming to obtain oximetric and metabolic parameters during NCS is frequently needed for intermediate- to high-risk NCS among HF patients. Furthermore, dynamic variables derived from the arterial pressure waveform (cardiac output, pulse pressure variation, stroke volume variation) are useful for guiding protocolled goal-directed therapy. Use of more invasive tools, such as right heart catheterization or transoesophageal echocardiography (TEE), might be considered on an individual patient level (see Section 7.1).

Baseline medication should be continued throughout the peri-operative period, in accordance with the recommendations provided in Section 5.2. It is recommended to perform ECG, measure biomarkers of myocardial injury (cTn T/I), and perform echocardiography to tailor the optimal treatment strategy in patients with acute decompensated HF post-operatively.

Table 11 Peri-operative approach to patients with ventricular assist devices undergoing non-cardiac surgery

Pre-operative	Intra-operative	Post-operative
<ul style="list-style-type: none"> • Multidisciplinary team identified (primary surgical and anaesthesia teams, cardiac surgery, HF cardiologist, VAD personnel) • Pre-operative medical optimization when possible or necessary • Physical examination focused on the sequelae of HF • Baseline ECG, echocardiogram, and laboratory values • Manage pacemaker/ICD settings when indicated • CT examination to evaluate possible driveline interference with the operative field • Hold, bridge, or reverse anticoagulation when indicated, after VAD team consultation 	<ul style="list-style-type: none"> • Standard American Society of Anesthesiologists monitors • Cerebral tissue oxygenation, processed electroencephalogram, arterial line with ultrasound guidance, central venous catheter if fluid shifts are expected, PA catheter only if severe pulmonary hypertension, TEE available • Monitor VAD control console • External defibrillator pads in place • Optimize pre-load, support RV function, avoid increase in afterload • Gradual peritoneal insufflations and position changes 	<ul style="list-style-type: none"> • Standard post-anaesthesia care unit unless ICU is otherwise indicated • Extubation criteria are unchanged • Avoid hypoventilation, optimize oxygenation • Resume heparin infusion when post-op bleeding risk is acceptable

Adapted from Roberts et al.⁴²¹

The management of patients with cardiac implantable electronic devices (CIEDs) undergoing NCS is discussed in [Section 6.4.5](#). In patients with resynchronization devices (cardiac resynchronization therapy [CRT]), it is recommended to keep the device on to provide better haemodynamic stability.

6.2.3. Hypertrophic obstructive cardiomyopathy

Patients with hypertrophic cardiomyopathy with LV outflow tract obstruction (HOCM) have an increased risk of complications during NCS and require additional attention.⁴¹⁸ It is recommended to perform TTE before NCS in order to determine the extent of the hypertrophy, obstruction, and diastolic function.⁴¹⁹ Avoidance of prolonged pre-operative fasting and dehydration is important to maintain stroke volume and reduce the risk of increased obstruction. Furthermore, it is important to avoid vasodilating anaesthetic agents and maintain neutral fluid balance during the peri-operative period. The heart rate should be kept low (60–65 beats per minute [b.p.m.]) and AF should be avoided. Medication used to treat LV outflow tract obstruction should remain on board during NCS.

6.2.4. Patients with ventricular assist devices undergoing non-cardiac surgery

Ventricular assist devices (VADs) play an important role in the treatment of patients with end-stage HF who require a bridge to heart transplantation or as a permanent destination therapy. As the number of patients receiving VAD as destination therapy increases,^{420,421} the need for NCS in this specific subset of patients is expected to increase in years to come. Non-cardiac surgery should be performed in surgical centres that have access to VAD teams ([Table 11](#)).

Recommendation Table 20 — Recommendations for management of heart failure in patients undergoing non-cardiac surgery

Recommendations	Class ^a	Level ^b
In patients with suspected or known HF scheduled for high-risk NCS, it is recommended to evaluate LV function with echocardiography and measurement of NT-proBNP/BNP levels, unless this has recently been performed. ^{112,113,422,423}	I	B
It is recommended that patients with HF undergoing NCS receive optimal medical treatment according to current ESC guidelines. ⁴¹²	I	A
In patients with HF undergoing NCS, it is recommended to regularly assess volume status and signs of organ perfusion.	I	C
A multidisciplinary team including VAD specialists is recommended for peri-operative management of patients with HF receiving mechanical circulatory support.	I	C

6.3. Valvular heart disease

6.3.1. Risk for patients with valvular heart disease

Valvular heart disease increases the risk of peri-operative CV complications during NCS. The magnitude of risk is highly

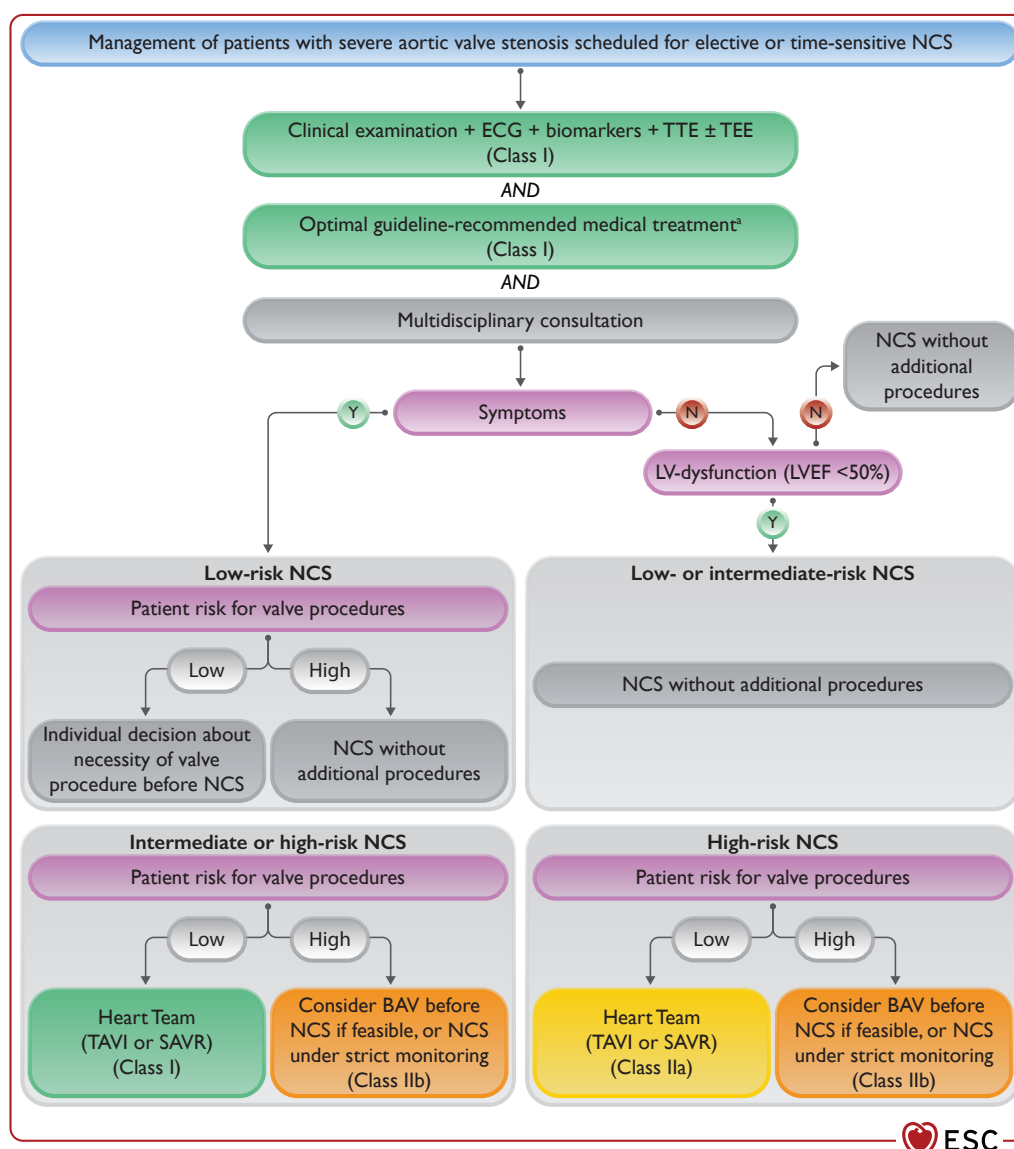

Figure 13 Management of patients with severe aortic valve stenosis scheduled for non-cardiac surgery. BAV, balloon aortic valvuloplasty; ECG, electrocardiogram; LV, left ventricular; LVEF, left ventricular ejection fraction; N, no; NCS, non-cardiac surgery; SAVR, surgical aortic valve replacement; TAVI, transcatheter aortic valve implantation; TTE, transthoracic echocardiography; TEE, transoesophageal echocardiography. Y, yes; The figure provides a schematic representation of diagnostic assessment or therapy to be implemented according to surgical risk and underlying cardiac condition. ^aThis applies to treatment of complications (e.g. atrial fibrillation, heart failure). No medical therapy is recommended for aortic stenosis per se.

variable and depends on the severity of VHD and type of NCS. It is particularly increased in patients with obstructive valve pathology, for example symptomatic AS or MS, where peri-operative volume shifts and arrhythmia may lead to rapid decompensation.⁴²⁴

6.3.2. Pre-operative management strategies and risk-reduction strategy

Clinical and echocardiographic evaluation is recommended in all patients with known or suspected VHD who are scheduled for elective intermediate-or-high-risk NCS. Patients in whom mild-to-moderate VHD was diagnosed >1 year earlier should have clinical and echocardiographic re-assessment. Heart team discussion may be helpful in patients with significant VHD. The risks of valvular intervention

and the risk of NCS-related complications should be estimated and communicated to the patient and the surgical team.

6.3.2.1. Aortic valve stenosis

The peri-operative risk associated with AS during NCS depends upon the presence of symptoms, stenosis severity, and coexisting cardiac disease (e.g. CAD, mitral insufficiency, or reduced LVEF). Severe symptomatic AS is a significant risk factor for post-operative MI and HF, and a predictor for 30 day and long-term mortality after NCS.^{425,426} Careful peri-operative management is essential in patients undergoing intermediate- and high-risk NCS, albeit the significance of AS in patients undergoing low-risk NCS might have been overemphasized in studies that pre-date the more recent advances in anaesthesia, surgical techniques, and post-operative management.

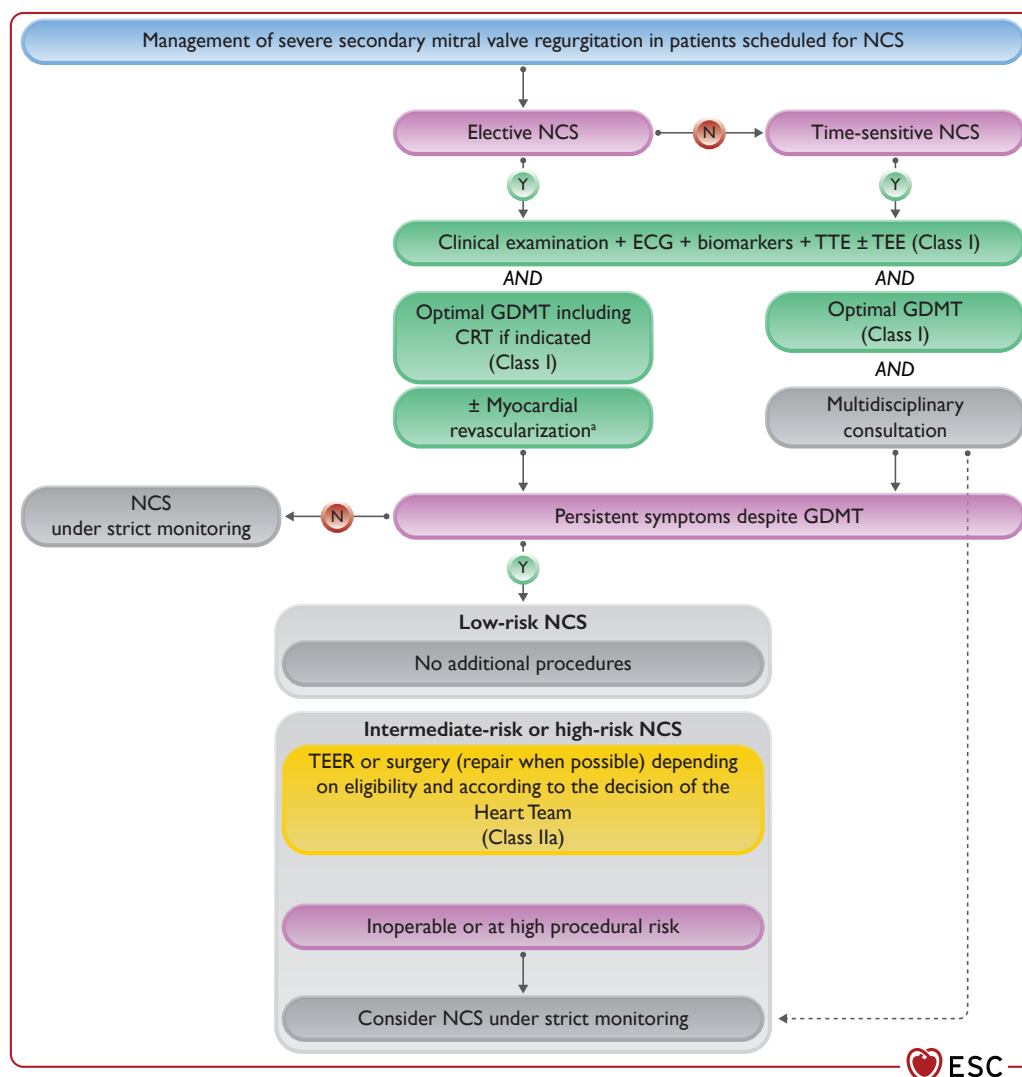

Figure 14 Management of patients with secondary mitral valve regurgitation scheduled for non-cardiac surgery. ECG, electrocardiogram; GDMT, guideline-directed medical therapy; N, no; NCS, non-cardiac surgery; TTE, transthoracic echocardiography; TEE, transoesophageal echocardiography; TEER, transcatheter edge-to-edge repair. Y, yes; ^aCoronary angiography ± PCI/CABG on a case-by-case according to the expert team.

Aortic valve replacement has been associated with reduced in-hospital and 30 day mortality and morbidity among patients with AS undergoing intermediate- to high-risk NCS.^{425,426} However, the decision regarding the timing of AVR in relation to NCS should be weighted according to the baseline risk profile and the risk associated with the NCS. The choice of surgical aortic valve replacement (SAVR) vs. TAVI should follow the 2021 ESC/EACTS Guidelines for the management of valvular heart disease²⁴⁵ and patient's informed preference (Figure 13).

In patients with severe symptomatic AS, in whom NCS can be deferred, aortic valve intervention (SAVR or TAVI) is recommended before NCS. In patients requiring time-sensitive NCS, TAVI is a reasonable option.⁴²⁷ In patients with severe symptomatic AS in need of time-sensitive NCS in whom TAVI or SAVR are unfeasible, balloon aortic valvuloplasty (BAV) may be considered before NCS as a bridge to definitive aortic valve repair. Asymptomatic patients with severe

AS and normal LVEF can safely undergo low- to intermediate-risk NCS, unless the NCS is associated with large volume shifts.^{245,428}

6.3.2.2. Mitral valve stenosis

Non-cardiac surgery can be performed with a relatively low risk of complications in patients with mild MS (valve area >1.5 cm²) and in asymptomatic patients with moderate-to-severe MS (valve area ≤ 1.5 cm²) and systolic pulmonary artery pressure (SPAP) <50 mmHg on echocardiography.⁴²⁹ As transmitral gradients are flow-sensitive, tachycardia and fluid overload can cause pulmonary oedema during NCS. In this regard, arterial vasodilators should be avoided and surveillance for peri-operative AF is of paramount importance. Management of anticoagulation for patients with high thrombotic risk is discussed in Section 5.3.2. In asymptomatic patients with moderate-to-severe MS and SPAP >50 mmHg, and in symptomatic patients, the peri-operative risk of CV events is increased.

In this case, a percutaneous mitral commissurotomy (PMC) should be considered before high-risk NCS. Otherwise, a multidisciplinary team should manage patients with moderate-to-severe MS who are ineligible for PMC, and NCS should be performed only if necessary. Intermediate-risk NCS may be performed in asymptomatic patients with severe MS with appropriate intra-operative and post-operative haemodynamic monitoring, if valve morphology is unsuitable for PMC.

6.3.2.3. Aortic valve regurgitation

In patients with mild-to-moderate aortic valve regurgitation (AR), NCS can be performed without additional risk. Patients with severe AR in whom valvular intervention is needed should be treated before intermediate-or-high-risk elective NCS (see [Recommendation Table 21](#) and the 2021 ESC/EACTS Guidelines for the management of valvular heart disease).²⁴⁵

6.3.2.4. Mitral valve regurgitation

In patients with severe symptomatic mitral valve regurgitation (MR), the type of valve disease (primary or secondary) and LV function should be assessed. Patients with secondary MR, especially of ischaemic aetiology, are at increased risk of CV complications during NCS.⁴³⁰ Patients with severe symptomatic MR fulfilling the intervention criteria should be referred for valve treatment before intermediate- or high-risk elective NCS. In case of symptomatic moderate-to-severe secondary MR, patients meeting the Cardiovascular Outcomes Assessment of the MitraClip Percutaneous Therapy for Heart Failure Patients With Functional Mitral Regurgitation (COAPT) criteria should be considered for transcatheter edge-to-edge treatment before NCS ([Figure 14](#)).^{245,431} In patients with severe primary MR with symptoms or asymptomatic with LV dysfunction, valve repair is the recommended therapy (see [Recommendation Table 21](#) and the 2021 ESC/EACTS Guidelines for the management of valvular heart disease²⁴⁵).

In patients with reduced LVEF and concomitant AR or MR, intra-operative haemodynamic monitoring, heart rate control, and careful fluid balance are crucial to avoid haemodynamic deterioration, especially during high-risk surgery.

Recommendation Table 21 — Recommendations for management of valvular heart disease in patients undergoing non-cardiac surgery

Recommendations	Class ^a	Level ^b
Clinical and echocardiographic evaluation (if not recently performed) is recommended in all patients with known or suspected VHD who are scheduled for elective intermediate- or high-risk NCS.	I	C
Aortic valve stenosis		
AVR (SAVR or TAVI) is recommended in symptomatic patients with severe AS who are scheduled for elective intermediate- or high-risk NCS.	I	C

Continued

In asymptomatic patients with severe AS who are scheduled for elective high-risk NCS, AVR (SAVR or TAVI) should be considered after Heart Team discussion.	IIa	C
In patients with severe symptomatic AS in need of time-sensitive NCS or in whom the TAVI and SAVR are unfeasible, BAV may be considered before NCS as a bridge to definitive aortic valve repair.	IIb	C
Aortic valve regurgitation		
In patients with symptomatic severe AR or asymptomatic severe AR and LVESD >50 mm or LVESDi (LVESD/BSA) >25 mm/m ² (in patients with small body size) or resting LVEF ≤50%, valve surgery is recommended prior to elective intermediate- or high-risk NCS.	I	C
Mitral valve stenosis		
In patients with moderate-to-severe rheumatic MS and symptoms or SPAP >50 mmHg, valve intervention (PMC or surgery) is recommended before elective intermediate- or high-risk NCS.	I	C
Mitral valve regurgitation		
In patients with symptomatic severe primary MR or asymptomatic severe primary MR with LV dysfunction (LVESD ≥40 mm and/or LVEF ≤60%), valve intervention (surgical or transcatheter) should be considered prior to intermediate- or high-risk NCS, if time allows.	IIa	C
In patients with severe secondary MR who remain symptomatic despite guideline-directed medical therapy (including CRT if indicated), valve intervention (transcatheter or surgical) should be considered before NCS, in eligible patients with an acceptable procedural risk.	IIa	C

AS, aortic valve stenosis; AR, aortic valve regurgitation; AVR, aortic valve replacement; BAV, balloon aortic valvuloplasty; BSA, body surface area; CRT, cardiac resynchronization therapy; LV, left ventricular; LVEF, left ventricular ejection fraction; LVESD, left ventricular end-systolic diameter; LVESDi, left ventricular end-systolic dimension index; MR, mitral valve regurgitation; MS, mitral stenosis; NCS, non-cardiac surgery; PMC, percutaneous mitral commissurotomy; SAVR, surgical aortic valve replacement; SPAP, systolic pulmonary artery pressure; TAVI, transcatheter aortic valve implantation; VHD, valvular heart disease.

^aClass of recommendation.

^bLevel of evidence.

6.3.2.5. Patients with prosthetic valve(s)

Patients who have undergone previous surgical correction of VHD and have a prosthetic valve can undergo NCS provided that there is no evidence of valve dysfunction. In current practice, the main problem is the need for a modification of the anticoagulation regimen in the peri-operative period; this is discussed in detail in [Section 5.3](#).

6.3.2.6. Prophylaxis of infective endocarditis

Prophylaxis against infective endocarditis in patients requiring NCS should be consistent with the 2015 ESC Guidelines for the management of infective endocarditis.⁴³²

6.4. Known or newly diagnosed arrhythmias

Arrhythmias pose a significant burden to patients undergoing NCS, contributing to excessive morbidity and mortality.^{433,434}

6.4.1. Peri-operative management—general measures

Arrhythmias—namely, supraventricular tachycardia (SVT) and ventricular tachycardia (VT)—may accompany acute surgical illness, but should not defer urgent surgical procedures, unless the arrhythmia is life-threatening. All patients with known arrhythmia undergoing elective surgery should have a 12-lead ECG performed pre-operatively and undergo a cardiology check-up. Prevention of potential arrhythmic triggers is crucial: electrolyte and acid-base imbalance, myocardial ischaemia (also caused by excessive blood loss and anaemia), and large volume shifts, which can provoke subsequent autonomic hyperactivity, should be avoided in the pre-, intra-, and post-operative periods. Patients with a systolic HF should receive optimal treatment, as such therapy reduces the risk of total mortality and sudden cardiac death (SCD).⁴³⁵ Patients already taking AADs should generally not stop taking these drugs. Patients at high-risk of malignant arrhythmias should have continuous ECG monitoring through the whole peri-operative period, with particular emphasis placed on patients who have had implantable cardioverter–defibrillators (ICDs) deactivated during NCS.

6.4.2. Supraventricular arrhythmias

Supraventricular arrhythmias do not usually cause deferral of surgery. In rare cases, presence of pre-excitation and AF conducted rapidly over an accessory pathway flag a patient at risk of SCD and may indicate the need for ablation, if surgery is not emergent.

Supraventricular premature beats usually do not require therapy. Identification and correction of potential triggers (electrolyte and acid-base imbalance, volume overload, etc.) are highly recommended. Peri-operative SVT typically responds well to vagal manoeuvres, or to a bolus of adenosine if unsuccessful. If SVT persists or reoccurs, i.v. beta-blockers, verapamil, or diltiazem can be used for rhythm conversion or temporal slowing of atrioventricular conduction.⁴³⁶ Prompt cardioversion should be performed in rare cases of haemodynamically unstable SVT. If prophylactic therapy is needed to prevent recurrent SVT, beta-blockers or non-dihydropyridine CCBs (verapamil, diltiazem) can be used, and flecainide/propafenone or amiodarone can be considered if ineffective. Rarely, when SVT recurs despite therapy or becomes incessant, ablation should be considered in patients undergoing high-risk, non-emergent surgery. Recently published results of an RCT confirmed the superiority of radiofrequency (RF) ablation over AADs for persistent atrioventricular nodal re-entry tachycardia. Large registries and meta-analyses have demonstrated efficacy and safety of RF ablation in WPW syndrome and other SVTs, with a single-procedure success rate of >90%.^{437–441}

6.4.3. Atrial fibrillation/flutter

The majority of patients with AF receive lifelong OAC therapy for the prevention of stroke and systemic embolism,⁹⁹ and the peri-operative management of OAC therapy will depend on the type

of surgery (see [Section 5.3.2](#)).^{99,240} Sometimes AF is asymptomatic⁴⁴² and may be first detected on admission for surgery, or may first occur in the pre-operative period. The initial management of newly diagnosed AF includes prevention of thromboembolism, and symptom control, and should not be deferred awaiting consultation with a cardiologist.⁹⁹ In patients with newly diagnosed AF who require systemic OAC therapy for stroke prevention, the choice of anticoagulant in the pre-operative period depends on the type of surgery (see [Section 5.3.2](#)). Optimal rate control (i.e. resting heart rate <110 b.p.m.)⁹⁹ is mandatory in all patients with AF, whereas rhythm control (i.e. achieving and maintenance of sinus rhythm) in the pre-operative period may be considered only if symptoms persist despite optimal rate control.

Rate control can be achieved using beta-blockers or non-dihydropyridine CCBs (verapamil, diltiazem). Amiodarone can be used as first-line therapy in patients with HF, whereas digoxin is usually ineffective in high adrenergic conditions such as surgery. Pharmacological cardioversion of symptomatic recent-onset AF can be attempted using flecainide or propafenone; in patients without significant LV hypertrophy, LV systolic dysfunction, or IHD, the use of flecainide or propafenone results in prompt (3–5 h) and safe restoration of sinus rhythm in >50% of patients. Intravenous amiodarone administration has a limited and delayed effect but can slow the heart rate within 12 h; i.v. vernakalant is the most rapidly cardioverting drug, including patients with mild HF and/or IHD.^{99,443} Dofetilide is not used in Europe, and ibutilide is effective to convert atrial flutter to sinus rhythm.^{99,444} In patients with AF and haemodynamic instability, emergency cardioversion (most commonly electrical direct current cardioversion) is indicated.⁹⁹ Alternatively, pharmacological cardioversion using i.v. AADs should be attempted, if consistent with the patient's clinical status. Systemic OAC therapy to prevent thromboembolic events should be started as soon as possible.⁹⁹ Post-operative AF is discussed in [Section 8.6](#).

Management of atrial flutter follows the same principles as AF with respect to OAC therapy. Rate control is usually an initial approach in patients with atrial flutter;⁴³⁶ however, drugs that slow atrioventricular conduction (digoxin, beta-blockers, or non-dihydropyridine CCBs) are usually less effective than in AF. In patients with a high ventricular rate, electrical cardioversion is frequently needed.^{445–448} Amiodarone may be an alternative used to control rate, especially in HF or critically compromised patients.⁴⁴⁹ Dofetilide and ibutilide are effective in converting atrial flutter to sinus rhythm, whereas class IA and IC drugs and amiodarone are less efficient and should not be used.^{450–453}

6.4.4. Ventricular arrhythmias

Premature ventricular contractions (PVC) and non-sustained VT are frequent in the general population and patients undergoing NCS. Specific clinical features have been suggested as predictors of increasing incidence of PVC.⁴⁵⁴ These arrhythmias have historically been considered benign; however, recent studies have suggested that they may be associated with an adverse outcome, even in patients with apparently normal hearts, especially if frequent (e.g. >10–20%).^{455–459} In patients with heart disease, the prognostic impact of PVC and non-sustained VT depends on type and extent of heart damage.^{460–466} In patients undergoing urgent NCS, they do not require treatment unless frequent and symptomatic.

Table 12 Peri-operative management of patients with arrhythmias

Type of arrhythmia	SVT	Idiopathic VT in structurally/functionally normal heart	VT in structural heart disease
Diagnostics	• ECG ± TTE ^a	• ECG ± TTE	• ECG + TTE + biomarkers ^b • ± Coronary angiography • ± Cardiac CT/MRI
Acute management	• Vagal manoeuvres • I.v. adenosine, beta-blocker, CCB • Electrical cardioversion if unstable	• Vagal manoeuvres • I.v. beta-blockers/ verapamil • Electrical cardioversion if unstable	• Treatment of underlying heart disease • I.v. beta-blocker (uptitration), amiodarone • Electrical cardioversion if unstable
Prevention of recurrence	• Per oral beta-blocker, CCB • Catheter ablation if recurrent despite OMT (only before high-risk NCS)	• No treatment or • Per oral beta-blocker, CCB, class I AAD • Catheter ablation in case of recurrence despite AADs or drug-intolerance before high-risk NCS	• Per oral beta-blocker, amiodarone • Catheter ablation if recurrent despite OMT

AAD, antiarrhythmic drug; CCB, calcium channel blocker; CT, computer tomography; ECG, electrocardiogram; MRI, magnetic resonance imaging; NCS, non-cardiac surgery; OMT, optimal medical therapy; SVT, supraventricular tachycardia; TTE, transthoracic echocardiography; VT, ventricular tachycardia.

^aBefore high-risk surgery.

^bHigh-sensitivity cardiac troponin T/I, and/or BNP/ N-terminal pro-BNP.

If haemodynamically compromising, up-titration of beta-blockers is recommended; amiodarone (300 mg i.v. bolus) should be considered if beta-blockers are not tolerated or contraindicated.⁴⁶⁷ Further diagnostics to rule out significant heart disease is necessary in patients awaiting elective NCS, especially if frequent, complex (non-sustained VT), symptomatic, or in those with a positive family history of SCD.

Polymorphic VT and ventricular fibrillation (VF) can be provoked by ischaemia, electrolyte imbalance, or may be manifestations of primary electrical disease, such as long-QT or Brugada syndrome. Monomorphic VT is often associated with the presence of scarred myocardium. Hence, peri-operative VT or VF in a patient awaiting surgery should lead to a diagnostic work-up to exclude severe ventricular dysfunction (see [Section 4.5.1](#)), and to rule out CAD requiring prompt revascularization (see [Section 6.1](#)) and other potential causes of arrhythmia (primary electrical disease, dyselectrolytaemia). Monomorphic VT in patients without overt structural or electrical heart disease (idiopathic VT, most commonly arising from outflow tract) is associated with good prognosis and may be left untreated or, if symptomatic, may be treated with beta-blockers, verapamil, or sodium channel blockers. Patients with haemodynamically compromising VT should undergo electrical cardioversion (after i.v. sedation, if conscious) and VF should be terminated with prompt defibrillation. Recurrent VT and VF in the setting of acute ischaemia may be effectively treated with beta-blockers and amiodarone, and myocardial revascularization in case of obstructive CAD.⁴⁶⁸ Up-titration of beta-blockers to the maximal tolerated doses can prevent arrhythmia recurrence.⁴⁶⁹

Haemodynamically stable, sustained VT should be cardioverted as a first-line treatment; i.v. procainamide or flecainide may be considered in patients without HF or myocardial ischaemia. In cases in which these drugs are unavailable, i.v. amiodarone can be used. In selected cases, when monomorphic VT recurs in patients with scarred

myocardium with no reversible causes, despite optimal therapy, invasive electrophysiological study and ablation should be performed pre-operatively, if NCS can be deferred. After extensive endocardial VT ablation, treatment with an OAC for a limited period of time might be reasonable.^{470,471} A summary of diagnostic and therapeutic pathways in patients with SVT or VT is shown in [Table 12](#).

Recommendation Table 22 — Recommendations for management of known or newly diagnosed arrhythmias

Recommendations	Class ^a	Level ^b
Supraventricular arrhythmias		
In patients with SVT controlled by medication, it is recommended that AADs are continued during the peri-operative period.	I	C
Ablation should be considered in symptomatic patients with recurrent or persistent SVT, despite treatment, prior to high-risk, non-urgent NCS. ^{437–441}	IIa	B
AF with haemodynamic instability in patients undergoing NCS		
In AF patients with acute or worsening haemodynamic instability undergoing NCS, emergency electrical cardioversion is recommended. ^{99,472,473}	I	B
In AF patients with haemodynamic instability, amiodarone may be considered for acute control of heart rate. ⁹⁹	IIb	B

Continued

Ventricular arrhythmias		
In patients with symptomatic, monomorphic, sustained VT associated with myocardial scar, recurring despite optimal medical therapy, ablation of arrhythmia is recommended before elective NCS. ^{474–480}	I	B
It is not recommended to initiate treatment of asymptomatic PVC during NCS.	III	C

AAD, antiarrhythmic drug; AF, atrial fibrillation; NCS, non-cardiac surgery; PVC, premature ventricular contractions; SVT, supraventricular tachycardia; VT, ventricular tachycardia.

^aClass of recommendation.

^bLevel of evidence.

6.4.5. Bradyarrhythmias

Temporary cardiac pacing during the peri-operative period should be limited to patients undergoing urgent NCS, if bradycardia is haemodynamically compromising despite i.v. chronotropic drugs, or provokes episodes of ventricular tachyarrhythmia.⁴⁸¹ In patients undergoing elective NCS, surgery should be deferred if possible, and permanent pacemaker should be implanted, if indications for pacing are fulfilled.⁴⁸¹ Prophylactic pacing in the settings of asymptomatic bifascicular block, with or without first-degree atrioventricular block, is generally not indicated, and chronotropic drugs (atropine, isoprenaline, adrenaline, or, alternatively, aminophylline, dopamine, or glucagon in beta-blocker or CCB overdosing) are usually effective. Patients with bifascicular bundle branch block or prolonged His-ventricular interval are at an increased risk of developing complete heart block.^{482,483} Equipment needed to perform emergent transcutaneous pacing and personnel able to perform such a procedure should be immediately available during NCS in patients with bifascicular block; alternatively, a permanent pacemaker may be implanted.⁴⁸¹

6.4.6. Management of patients with cardiac implantable electronic devices

Patients with CIEDs can undergo NCS, pending adequate peri-operative device management. A pre-operative check should have been performed at least once within the 12 months preceding surgery for pacemaker patients and within 6 months for patients with ICD, in the absence of any malfunction (remote monitoring can also be used for check-ups).^{484,485} In pacing-dependent patients, patients with biventricular pacing for CRT, and ICD-recipients undergoing elective NCS associated with risk of electromagnetic interference (EMI) (e.g. involving the use of unipolar electrocoagulation, especially above the umbilicus), CIED check and reprogramming should be performed immediately before surgery. In pacemaker-dependent patients, devices should be reprogrammed to non-sensing or asynchronous pacing mode to protect against inhibition of the pacemaker. This can be performed in the majority of pacemaker models by placing a magnet over the pacemaker can.^{486,487} However, magnet mode in modern pacemakers, except Medtronic and Sorin/Livanova/Microport, is programmable and may not be asynchronous pacing; thus, magnet application is not a universal remedy against EMI-induced malfunction. Furthermore, asynchronous

pacing may lead to pacing on the T wave, which can provoke VT/VF. However, the risk of clinically significant EMI is low^{487–489} and a practical solution would be to monitor the patient via plethysmography or an arterial line, and limit the use of electrocautery if pauses occur during ECG monitoring.

Patients with leadless pacemakers may safely undergo surgery, with precautions similar to patients with conventional pacemakers, avoiding EMI and after reprogramming the pacemaker into non-sensing mode in pacing-dependent patients (due to its intracardiac location and lack of a Hall-effect sensor/reed switch, this device cannot be temporarily reprogrammed to an asynchronous mode with a magnet applied over the body of the pacemaker).^{490,491}

In patients with ICDs undergoing NCS with anticipated risk of EMI, arrhythmia detection or antiarrhythmic therapies through the device should be switched off before NCS,⁴⁹² or a magnet should be put over the device.^{488,489,492} All modern ICDs will respond to magnet application by inhibiting antitachycardia therapy, while the brady pacing is left intact. Deactivation by programming mandates telemetry and cardioversion equipment until reactivation, which may be impractical. Furthermore, there is a risk that the patient is discharged without the device being reactivated. These factors would favour the use of a magnet instead of deactivation. In some patients where the device is inaccessible for magnet application, a magnet cannot be used and reprogramming is mandatory. From this point onwards, throughout the whole procedure until reactivation of the ICD, the patient should have continuous ECG monitoring, and personnel skilled in early detection of arrhythmias, defibrillation, and cardiopulmonary resuscitation manoeuvres should be present. As soon as possible after NCS, it is recommended that the ICD is checked and therapies switched on.⁴⁸⁵

Patients with subcutaneous ICD can undergo surgery after switching off the antiarrhythmic therapy or magnet application; however, if thoracic surgery is planned, especially with a median sternotomy, the surgeon should be aware of the presence of the ICD and the course of the subcutaneous electrode. This can prevent mechanical damage of the lead, the direct use of electrocautery on the electrode, or the placement of sternal wires in close proximity to the sensing electrodes.⁴⁹³

In pacing-dependent patients, patients with CRT, and ICD patients, EMI with the device should be avoided (e.g. with electrocautery). Use of bipolar electrocautery, short bursts of impulses limited to several seconds (<5 s), with the lowest effective energy, and operating with a pen or stylus away from the device (>15 cm) can minimize the risk of interference with the device. In the case of unipolar electrocoagulation, the electrosurgical unit should be connected in a way that keeps the current circuit away from the CIED can and electrodes. However, the manufacturer's recommendations should be considered (usually recommending placement of the indifferent electrode on the opposite site of the body to the one operated on, but possibly close to the surgical site, on a well-vascularized, muscular area). Consequently, the indifferent return pad should be placed as far away from the CIED as possible, keeping the surgical site between the CIED and the return electrode (Figure 15).^{494–497}

In patients with implantable loop recorders (especially those not undergoing remote monitoring and regular downloads of the CIED memory), the device memory download is to be considered

© ESC 2022

Figure 15 Optimal location of return electrode during unipolar electrosurgery in patients with cardiac implantable electronic devices, depending on the surgery site. CIED, cardiac implantable electronic device. Use of bipolar electrocautery, short (<5 s) bursts of impulses, with the lowest effective energy, operating with pen or stylus away (>15 cm) from the device can minimize the risk of interference with the device. before procedures associated with possible EMI, or involving the anatomical location close to the device, to avoid misrecognizing and recording noise as arrhythmia or erasing the memory.^{498,499}

Recommendation Table 23 — Recommendations for management of bradyarrhythmia and patients carrying cardiac implantable devices

Recommendations	Class ^a	Level ^b
If indications for pacing exist according to the 2021 ESC Guidelines on cardiac pacing and cardiac resynchronization therapy, ⁴⁸¹ NCS surgery should be deferred and implantation of a permanent pacemaker should be considered.	IIa	C
It is recommended that patients with temporarily deactivated ICDs have continuous ECG monitoring, and during the peri-operative period are accompanied by personnel skilled in early detection and treatment of arrhythmias. In high-risk patients (e.g. pacemaker-dependant or ICD patients), or if access to the torso will be difficult during the procedure, it is recommended to place transcutaneous pacing/defibrillation pads prior to NCS.	I	C
It is recommended that all patients with CIEDs that are reprogrammed before surgery have a re-check and necessary reprogramming as soon as possible after the procedure.	I	C

Continued

In high-risk CIED patients (e.g. with ICD or being pacing-dependant) undergoing NCS carrying a high probability of electromagnetic interference (e.g. involving unipolar electrosurgery above the umbilical area), CIED check-up and necessary reprogramming immediately before the procedure should be considered.

^bLevel of evidence.

6.5. Adult congenital heart disease

Adults with congenital heart disease (ACHD) account for >60% of the population with congenital heart disease (CHD).^{500,501} Accordingly, ACHD represent an increasing proportion of NCS admissions⁵⁰² and might be at high risk of CV events.

Pre-operative risk assessment in ACHD needs to focus on the underlying disease, type of surgery, residua, and sequelae.⁵⁰³ Coexistence of HF, pulmonary hypertension, arrhythmia, hypoxaemia, damage to other organs, and endocarditis may considerably influence the baseline risk of these patients from no additional risk to very high risk of worse prognosis.^{503,504} Thus, original medical and surgical reports should be obtained along with current data, which should include symptoms, exercise capacity, oxygen saturation, laboratory values (BNP, haemoglobin, creatinine, etc.), and medication.

Table 13 Risk stratification for non-cardiac surgery in adults with congenital heart disease

Minor risk	Patients with small, uncorrected defects, and no need for medication or any other treatment Patients with successfully corrected CHD with no symptoms, no relevant residua, and no need for medication
Intermediate risk	Patients with corrected or uncorrected conditions with residual haemodynamic abnormality, with or without medication
Severe risk	Patients with uncorrected cyanotic heart disease, pulmonary hypertension, other complex CHD, ventricular dysfunction requiring medication, and patients listed for heart transplantation

CHD, congenital heart disease.

In a recent report, absolute mortality in ACHD patients undergoing NCS exceeded 4%.⁵⁰² Mortality and peri-operative morbidity were greater in ACHD compared with a matched comparison cohort, and patients with severe ACHD had the highest mortality rate. It is well known that patients with pulmonary hypertension and with Eisenmenger syndrome have a higher risk of complications.⁵⁰⁵ A large registry confirmed these findings: patients with severe CHD had an increased risk of 30 day mortality, overall mortality, and reintubation, while patients with intermediate CHD had a moderate increase in overall mortality and risk of reintubation.⁵⁰⁶ Based on this study and recent guidelines,⁵⁰³ the classification in Table 13 is proposed for risk stratification.

A consultation by an ACHD specialist is necessary, especially in patients with intermediate or severe ACHD scheduled for intermediate- or high-risk NCS. It is recommended that elective surgery in intermediate- and severe-risk ACHD patients should take place in centres experienced in the management of ACHD patients. It is generally recommended to perform the least invasive procedures and anaesthesia with as low an impact on haemodynamics as possible.

Optimal peri-operative care in ACHD undergoing NCS starts with a proper pre-operative evaluation. Adults with congenital heart disease can present with multiorgan involvement (kidneys, liver, lung, and endocrine system), which should be considered during the diagnostic work-up.⁵⁰³ In many cases, patients with ACHD have a lifelong indication for OAC therapy or antithrombotic treatment, mainly due to arrhythmias or increased thromboembolic risk associated with specific ACHD. Oral anticoagulant therapy in the peri-operative phase should be re-evaluated on a case-by-case basis. The CHA₂DS₂-VASc score has not been validated in ACHD patients and should not be used in this group.

Continuous haemodynamic monitoring can be necessary in patients with ACHD and should include invasive BP monitoring, especially in cases with ACHD of moderate or severe complexity. It is worth mentioning that, according to the type of ACHD or surgery (e.g. coarctation of the aorta or following a Blalock-Taussig shunt), the location of the arterial line for continuous BP and gas exchange monitoring requires careful attention. In patients with persistent

right-to-left shunts, air filters must be used for venous access. Ventilator management and extubation can be complicated by the presence of restrictive lung disease.⁵⁰⁷ Antibiotic prophylaxis for endocarditis should be given according to the 2015 ESC Guidelines for the management of infective endocarditis.⁴³² Furthermore, post-operative care in an ICU with experience in handling ACHD patients is often necessary.

A prolonged monitoring period in this setting should be considered, with a special focus on arrhythmias and an optimal volume management, as it has been shown that up to 50% of adverse events were attributable to lapses in the post-operative monitoring and care.⁵⁰⁸ Two groups at special risk are patients with chronic cyanosis and those after the Fontan procedure. Chronic cyanosis is associated with multiorgan involvement. Furthermore, bleeding risk is higher due to multiple collaterals, platelet dysfunction, and alterations in the coagulation cascade.⁵⁰⁹ In patients with Eisenmenger syndrome, conditions that increase pulmonary vascular resistance such as hypothermia, metabolic acidosis, hypercapnia, and hypovolaemia must be avoided.⁵⁰⁹ This is also true for patients after the Fontan procedure, where venous return relies on low pulmonary pressures. If intra-abdominal pressure rises too high in these patients, venous return is drastically reduced, with a subsequent drop in cardiac output. These haemodynamic aspects should be carefully considered in cases of laparoscopic or open NCS.

Recommendation Table 24 — Recommendations for management of patients with adult congenital heart disease undergoing non-cardiac surgery

Recommendations	Class ^a	Level ^b
In patients with ACHD, a consultation with an ACHD specialist is recommended before intermediate- or high-risk surgery.	I	C
In patients with ACHD, it is recommended that intermediate- and high-risk elective surgery is performed in a centre with experience in the care of ACHD patients.	I	C

6.6. Pericardial diseases

Active pericardial disease is infrequent at the time of NCS, but potentially life-threatening. The clarification of underlying aetiology is of utmost importance for peri-operative management (viral or bacterial infection, malignant, systemic autoimmune, metabolic, or autoimmune disease). The treatment of these conditions should follow the recommendations provided in the 2015 ESC Guidelines for the diagnosis and management of pericardial diseases.⁵¹⁰

Acute pericarditis is a clear indication to postpone an elective surgical procedure. However, in cases of undeferrable NCS, attention is required regarding drug-to-drug interactions. The frequently used colchicine is predominantly metabolized through the liver, while renal excretion accounts for only 10–20%. Colchicine may increase

© ESC 2022

© ESC 2022

sensitivity to central nervous system depressants and exert a respiratory depressant effect.⁵¹¹ Adverse events of peri-operative significance include diarrhoea, worsening renal failure, and, very rarely, bone marrow suppression, hepatotoxicity, paralysis, convulsions, and cardiopulmonary collapse. Immunosuppressive drugs such as steroids and interleukin-1 receptor antagonist agents suppress the immune system, and may increase the risk of infection and delay wound healing in the peri-operative phase.⁵¹¹

Imminent cardiac tamponade is an absolute contraindication for all surgical procedures, especially when a general anaesthesia is required.^{510,512} Before NCS, pericardial effusion should first be percutaneously drained, under local anaesthesia. In cases of small or moderate chronic pericardial effusion and constrictive pericarditis, attention should be paid to take measurements to increase cardiac pre-load. The pre-load should be optimized peri-operatively with i.v. fluids prior to general anaesthetic induction to facilitate ventricular filling. Manipulation and medication diminishing venous return to the heart should be avoided or minimized. Positive pressure ventilation might cause a dramatic decline in pre-load and should be avoided. If spontaneous breathing is not possible, ventilation with minimal inspiratory pressures (low tidal volumes, high respiratory rate) should be considered. Anaesthetics that minimize changes in heart rate, systemic vascular resistance, venous return, and myocardial contractility should be selected.¹⁸⁹ Ketamine, a sympathetic stimulant that preserves spontaneous ventilation, is the drug of first choice. Combinations of opiates, benzodiazepines, and nitric oxide, with or without low doses of volatile anaesthetics, are acceptable for maintenance of anaesthesia. Muscle relaxants with minimal circulatory effects should be preferred, although the modest increase in heart rate observed with administration of pancuronium is also acceptable.

Recommendation Table 25 — Recommendations for pericardial diseases

Recommendations	Class ^a	Level ^b
In patients with acute pericarditis, deferring elective NCS until complete resolution of the underlying process should be considered.	IIa	C
Avoiding elective NCS procedures under general anaesthesia until colchicine or the immunosuppressive treatment course for pericardial disease is completed may be considered.	IIb	C

6.7. Pulmonary disease and pulmonary arterial hypertension

The coexistence of pulmonary disease in cardiac patients undergoing NCS may increase the operative risk. Pre-existing pulmonary disease has a significant impact on peri-operative risk, but the most common

effect is an increase in the risk of post-operative pulmonary complications. These complications particularly occur after abdominal or thoracic surgery, and the risk seems to be increased in smokers. Certain respiratory conditions are associated with CV pathology and may require special cardiac risk assessment and management, in addition to dealing with the pulmonary disease per se. Three such conditions are chronic obstructive pulmonary disease (COPD), obesity hypoventilation syndrome, and pulmonary arterial hypertension (PAH).

6.7.1. Pulmonary disease

Chronic obstructive pulmonary disease is as a major cause of morbidity and mortality.⁵¹³ Although patients with COPD have an increased risk of CVD, there is no evidence that COPD is related to a higher risk of peri-operative cardiac complications. However, post-operative pulmonary complications result in significant mortality and morbidity. Pre-operative evaluation, using specific post-operative pulmonary complication tools, can be used to stratify at-risk patients and enable optimal pre-operative and peri-operative management.⁵¹⁴ In patients with COPD undergoing NCS, the pre-operative treatment goals are to optimize pulmonary function and minimize post-operative respiratory complications; this includes using the pre-operative period for education, including possible cessation of smoking (2 months before surgery), instruction concerning chest physiotherapy and lung expansion manoeuvres, muscular endurance training, and re-nutrition if required. Beta-adrenergic agonists and anticholinergic agents should be continued until the day of surgery in all symptomatic COPD patients with bronchial hyper-reactivity. In some cases, short-term systemic/inhaled steroids may be considered. Where there is active pulmonary infection, appropriate antibiotics should be administered for at least 10 days and, if possible, elective NCS should be deferred.⁵¹⁵

Obesity hypoventilation syndrome is defined as the triad of obesity, daytime hypoventilation, and sleep-disordered breathing. Although distinct from simple obesity and sleep apnoea, it is estimated that 90% patients with obesity hypoventilation syndrome also have obstructive sleep apnoea (OSA). The prevalence of obesity hypoventilation syndrome is 0.15–3% of adults and 7–22% in patients undergoing bariatric surgery.⁵¹⁶ Obesity hypoventilation syndrome is associated with even higher morbidity, including HF (and obesity-related cardiomyopathy), angina pectoris, pulmonary hypertension (30–88%) and cor pulmonale, and increased peri-operative mortality.⁵¹⁶ Patients at high risk of obesity hypoventilation syndrome who are undergoing NCS should be referred for additional specialist investigation of sleep-disordered breathing and pulmonary hypertension, with pre-operative initiation of appropriate positive airway pressure therapy, and planning of peri-operative techniques (anaesthetic and surgical) and post-operative positive airway pressure management within an appropriate monitored environment.^{516,517}

6.7.2. Pulmonary arterial hypertension

Pulmonary arterial hypertension is associated with increased morbidity and mortality in patients undergoing NCS.⁵¹⁸

Table 14 Patient-related and surgery-related factors to be considered when assessing peri-operative risk in patients with pulmonary arterial hypertension

Patient-related peri-operative risk factors in patients with PAH	Surgery-related peri-operative risk factors in patients with PAH
<ul style="list-style-type: none">• Functional class >II• Reduced six-minute walk distance• Coronary heart disease• Previous pulmonary embolism• Chronic renal insufficiency• Severe right ventricular dysfunction	<ul style="list-style-type: none">• Emergency surgery• Duration of anaesthesia >3 h• Intra-operative requirement for vasopressors

PAH, pulmonary arterial hypertension.
Adapted from Olsson et al.⁵²²

A meticulous pre-operative diagnostic work-up in this subset of patients should include assessment of functional status and severity of disease, in addition to comorbidities and the type of NCS. Echocardiography and right heart catheterization (if clinically indicated) are key components in the pre-operative work-up. The morbidity and mortality associated with PAH derive from the haemodynamic response of the right ventricle to acute increases in afterload.⁵¹⁹

In patients with severe PAH, peri-operative mortality ranging between 3–18% has been reported, depending on the severity of the underlying disease, and the nature and urgency of the surgical procedure. Emergency procedures are also associated with a high risk of complications.^{520,521} Patient-related and surgery-related factors should be considered when assessing peri-operative risk in patients with PAH (Table 14).⁵²² Owing to the potential for anaesthesia and surgery to be complicated by acute right HF and pulmonary hypertensive crisis, elective NCS in patients with PAH should be adequately discussed in a multidisciplinary team. Ideally, patients with PAH undergoing NCS should have optimal medical treatment before surgery and be managed in a centre experienced in PAH. Patients scheduled for NCS should be discussed by a pneumologist, cardiologist, surgeon, and an anaesthesiologist.⁵²³ The management of patients with PAH in the peri-operative setting should follow the recommendations provided in the 2022 ESC/ERS Guidelines for the diagnosis and treatment of pulmonary hypertension.⁵²⁴

Several novel therapies aimed at reducing pulmonary pressures are used pre-operatively in patients undergoing NCS. Of these therapies, endothelin receptor antagonists, phosphodiesterase inhibitors, and prostacyclin analogues are the most used.⁵²⁵ This medication should be continued during the peri-operative phase because therapy disruption may lead to a critical rebound of the PAH. Inhaled nitric oxide allows selective pulmonary vasodilatation with rapidity of action and it can be given to patients

Recommendation Table 26 — Recommendations for patients with pulmonary arterial hypertension undergoing non-cardiac surgery

Recommendations	Class ^a	Level ^b
It is recommended to continue chronic therapy for PAH in the peri-operative phase of NCS.	I	C
It is recommended that haemodynamic monitoring of patients with severe PAH continues for at least 24 h in the post-operative period.	I	C
In the case of progression of right HF in the post-operative period in patients with PAH, it is recommended that the diuretic dose be optimized and, if necessary, i.v. prostacyclin analogues be initiated under the guidance of a physician experienced in the management of PAH.	I	C
Inodilator drugs (dobutamine, milrinone, levosimendan), which increase cardiac output and lower pulmonary vascular resistance, should be considered peri-operatively according to the haemodynamic status of the patient.	IIa	C

who develop worsening pulmonary hypertension post-operatively to maintain right ventricular (RV) function and haemodynamic stability.⁵²⁶

6.8. Arterial hypertension

The prevalence of arterial hypertension in adults in Europe is ~30–45%.⁵²⁷ Of these patients, <40% have well-controlled BP (<140/90 mmHg). A large observational study has shown that patients with untreated hypertension 1 month before surgery had a 69% increased risk of 90 day post-operative mortality.¹⁸³ Further, overall CV risk assessment, including the search for hypertension-mediated organ damage, is of paramount importance in hypertensive patients, and mandatory when there is newly detected BP elevation.⁵²⁸

Postponing surgery is usually not advised in patients with grade 1 or 2 hypertension. In contrast, in subjects with a systolic BP ≥180 mmHg and/or diastolic BP ≥110 mmHg, deferring the intervention until BP is under control is advisable, except for emergency surgery.^{236,527,529,530} It also seems important to avoid large peri-operative BP fluctuations. In a recent randomized trial among patients undergoing abdominal surgery, an individualized intra-operative treatment strategy with systolic BP values kept within a 10% difference from the pre-operative office measurement resulted in a reduced risk of post-operative organ dysfunction.⁵²⁸ In a meta-analysis including 130 862 patients undergoing surgery, intra-operative hypotension was associated with

increased risk of morbidity (OR, 2.08; 95% CI, 1.56–2.77), mortality (OR, 1.94; 95% CI, 1.32–2.84), cardiac complications (OR, 2.44; 95% CI, 1.52–3.93), and AKI (OR, 2.68; 95% CI, 1.31–5.55).⁵³¹ In patients with hypertension, hypoperfusion may occur at higher BP levels and peri-operative BP control should be tailored to pre-operative levels.⁵²⁸

In patients referred for elective NCS, control of BP should be prioritized, especially in patients with systolic BP >160 mmHg. The management of patients with hypertension in the pre-operative setting should follow the recommendation provided in the 2018 ESC/European Society of Hypertension (ESH) Guidelines for the management of arterial hypertension.⁵²⁹ These guidelines advocate an approach using RAAS inhibitors (in patients aged <70 years) or CCBs (in patients aged >70 years) as single therapy in moderate hypertension and both in combination where dual therapy is needed, adding a diuretic and an aldosterone antagonist if additional medication is needed for adequate control. Beta-blockers are restricted to patients where it is specifically indicated.⁵²⁹ In patients with hypertension and a clear indication for beta-blocker, third-generation beta-blockers—such as carvedilol, celiprolol, labetalol, and nebivolol—have superior antihypertensive effects compared with other beta-blockers and fewer adverse effects, but there are no RCTs reporting outcomes in hypertensive patients.⁵²⁹ In a large observational study, a beta-blocker prescription prior to NCS was associated with lower 30 day mortality in patients with three or four cardiac risk factors.¹⁸⁸ However, for patients with no cardiac risk factors, the risk of death was significantly increased with beta-blockers.^{188,532}

Most patients with stage 3 hypertension on the day of surgery will be classified as hypertensive urgencies. In these cases, the 2018 ESC/ESH Guidelines for the management of arterial hypertension recommend ACEIs, CCBs, or diuretics. Neither ACEIs nor diuretics are recommended on the day of surgery. The use of CCBs is supported by a meta-analysis of 11 studies of CCBs during NCS.²²⁰ Further, a study of 989 well-controlled patients with hypertension without hypertension-related organ damage, testing the use of fast-acting nasal nifedipine when stage 3 hypertension (systolic BP >180 and/or diastolic BP >110 mmHg) was diagnosed the day of NCS, found no difference in outcome between administration of nifedipine and surgery on the same day compared with deferral for hypertension control before resuming surgery.⁵³³ Immediate nifedipine treatment was associated with shorter hospital stays. As this was the first study testing the need for deferral of stage 3 hypertension, it challenged the need for this practice. For patients with hypertensive emergencies (systolic BP >180 and/or diastolic BP >110 mmHg and organ damage), the 2018 ESC/ESH Guidelines for the management of arterial hypertension recommend labetalol, nitroglycerin, nitroprusside, etc., according to the affected organ.⁵²⁹

The timing of administration of the antihypertensive drugs, and their continuation or discontinuation in the peri-operative period is discussed in [Section 5.2](#).

Recommendation Table 27 — Recommendations for pre-operative management of hypertension

Recommendations	Class ^a	Level ^b
In patients with chronic hypertension undergoing elective NCS, it is recommended to avoid large peri-operative fluctuations in blood pressure, particularly hypotension, during the peri-operative period. ^{528,531}	I	A
It is recommended to perform pre-operative screening for hypertension-mediated organ damage and CV risk factors in newly diagnosed hypertensive patients who are scheduled for elective high-risk NCS.	I	C
It is not recommended to defer NCS in patients with stage 1 or 2 hypertension.	III	C

CV, cardiovascular; NCS, non-cardiac surgery.

^aClass of recommendation.

^bLevel of evidence.

6.9. Peripheral artery disease

Patients with peripheral artery disease (PAD) usually have advanced atherosclerotic disease affecting multiple vascular beds in varying degrees and have a worse prognosis compared with patients without PAD.^{534–538} Patients with PAD generally differ in their risk profiles, according to whether they undergo vascular or non-vascular NCS.

6.9.1. Peripheral artery disease and non-vascular non-cardiac surgery

Decisions on pre-operative treatment of pre-existing PAD and AAA in patients scheduled for non-vascular NCS should be made on an individual basis, taking into account symptoms and risks of surgery. Non-cardiac surgery should be prioritized in patients needing revascularization for PAD, but careful peri-operative monitoring of deterioration in lower extremity perfusion is warranted, particularly in those patients with chronic limb-threatening ischaemia (e.g. peripheral BP of ≤50–70 mmHg in the foot joint and ≤30–50 mmHg in the toes).⁵³⁹ For patients with AAA, pain control is essential to ensure stable BP, minimizing rupture risk. Patients with large AAA (i.e. >5 cm in diameter for women and >5.5 cm for men) should be evaluated for aortic aneurysm repair (preferably EVAR)^{540–542} before non-vascular NCS is planned, particularly in the case of malignant tumours, depending on the stage of malignant disease.

6.9.2. Peripheral artery disease and vascular non-cardiac surgery

The 2017 ESC Guidelines on the diagnosis and treatment of peripheral arterial diseases⁵³⁵ and the European Society for Vascular Surgery (ESVS) 2019 Clinical Practice Guidelines on the management of abdominal aorto-iliac artery aneurysms³⁵ provide detailed evidence and recommendations on the screening of patients before vascular

NCS and their treatment modality selection. Notably, there is randomized evidence against prophylactic coronary revascularization before major vascular surgery in CCS patients due to lack of benefit in improvement of peri-operative and long-term outcomes (2.7 years mean follow-up).³⁹⁹ Assessment of functional capacity might offer guidance to select candidates for cardiac assessment prior to major NCS, although severe walking impairment may challenge this test. The previously established risk predictive model to detect mortality in patients undergoing elective AAA repair may be helpful.⁵⁴³ Low-dose rivaroxaban plus aspirin initiated within 10 days after a lower limb revascularization procedure reduces post-operative thrombotic events (acute limb ischaemia, amputation, MI, ischaemic stroke, and CV death) in patients undergoing lower limb revascularization, whether it is carried out using an endovascular or open surgical approach.⁵⁴⁴ Handling of other co-drugs should follow the recommendations detailed in [Section 5.2](#).

Recommendation Table 28 — Recommendations for management of patients with peripheral artery disease and/or abdominal aortic aneurysm undergoing non-cardiac surgery

Recommendations	Class ^a	Level ^b
In patients with poor functional capacity or significant risk factors or symptoms (such as moderate-to-severe angina pectoris, decompensated HF, valvular disease, and significant arrhythmia), referral for cardiac work-up and optimization is recommended prior to elective surgery for PAD or AAA.	I	C
Routine referral for cardiac work-up, coronary angiography, or CPET prior to elective surgery for PAD or AAA is not recommended.	III	C

AAA, abdominal aortic aneurysm; CPET, cardiopulmonary exercise testing; HF, heart failure; PAD, peripheral artery disease.

^bLevel of evidence.

6.10. Cerebrovascular disease

Patients undergoing NCS should be questioned about previous neurological symptoms, and those with symptoms suggestive of transient ischaemic attack (TIA) or stroke in the preceding 6 months should undergo pre-operative neurological consultation and neurovascular and brain imaging, if appropriate. In the absence of dedicated studies addressing this issue, the criteria for carotid revascularization in symptomatic and asymptomatic patients is described in detail in the 2017 ESC Guidelines on the diagnosis and treatment of peripheral arterial diseases, in collaboration with the ESVS; these guidelines should also guide the management of patients with carotid disease who are undergoing NCS.⁵³⁵

In patients with symptomatic carotid disease, the benefit of carotid revascularization is particularly high in patients with recent (<3 months) TIA or stroke, and ≥70% carotid artery stenosis. Thus, carotid revascularization should be performed first and elective NCS should be postponed.⁵⁴⁵

The question as to whether patients with severe asymptomatic carotid occlusive disease who are undergoing elective major NCS require pre-operative carotid revascularization remains a matter of

debate. Importantly, the purpose of carotid revascularization in this setting is more the long-term prevention of stroke than peri-operative stroke risk reduction; therefore, if carotid revascularization is indicated, this may be performed before or after the planned NCS. Independent of the revascularization strategy, patients with carotid artery stenosis benefit from aggressive CV risk-factor modification to prevent peri-operative myocardial ischaemia.

Recommendation Table 29 — Recommendations for management of patients with suspected or established carotid artery disease undergoing non-cardiac surgery

Recommendations	Class ^a	Level ^b
Pre-operative carotid artery and cerebral imaging is recommended in patients with a history of TIA or stroke in the previous 6 months and who have not undergone ipsilateral revascularization.	I	C
For patients with carotid artery disease undergoing NCS, the same indications for carotid revascularization should be considered as for other patients with carotid stenosis.	IIa	C
Pre-operative carotid artery imaging is not recommended routinely in patients undergoing NCS.	III	C

NCS, non-cardiac surgery; TIA, transient ischaemic attack.
^aClass of recommendation.
^bLevel of evidence.

6.11. Renal disease

Renal disease is associated with several cardiac comorbidities, including hypertension, HF, CAD, and arrhythmias.⁵⁴⁶ Consistently, renal disease portends a significant increase in the post-operative risk of CV events, including MI, stroke, and progression of HF in patients undergoing NCS. For this reason, most risk indices for the quantification of pre-operative risk in patients undergoing NCS include renal function.

Chronic kidney disease (CKD) is defined as impaired kidney function or raised proteinuria, confirmed on two or more occasions at least 3 months apart. The kidney function can be assessed through the estimated glomerular filtration rate (eGFR) calculated using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula, including sex, age, ethnic origin, and serum creatinine concentration. A cut-off glomerular filtration rate (GFR) value <60 mL/min/1.73 m² significantly correlates with MACEs. Identification of cardiac patients at risk of worsening of renal function in the peri-operative phase of NCS is of paramount importance, in order to initiate supportive measures such as maintenance of adequate intravascular volume for renal perfusion and use of vasopressors.⁵⁴⁷

Patients with cardiac comorbidities are prone to develop AKI after major NCS, due to worsening of haemodynamic status associated with fluids or blood loss, and withdrawal or continuation of cardio-active therapies. The peri-operative management of patients undergoing NCS and treated with cardio-active drugs has been discussed in [Section 5.2](#). Acute kidney injury reduces long-term survival in patients with normal baseline renal function.⁵⁴⁸ Of interest, ~30–40% of all cases of AKI occur after surgery and the incidence of post-operative AKI ranges 18–47%. Risk factors for the development of post-operative AKI following NCS include cardiac

(decompensated or chronic HF, hypertension, cardio-active drugs) and non-cardiac triggers (age, sex, emergent, and/or intraperitoneal surgery, mild pre-operative renal insufficiency, pre-operative creatinine elevation, CKD, and DM).^{549,550} The combination of a low cardiac output/high venous pressure and/or the administration of iodinated contrast media during diagnostic and operative procedures represent the most frequent causes of AKI in hospitalized cardiac patients, regardless of pre-existing impaired renal function. Contrast-induced AKI is defined as a rise in serum creatinine of 44 mmol/L (0.5 mg/dL) or a 25% relative rise from baseline at 48 h (or 5–10% at 12 h) following contrast administration. It occurs in up to 15% of patients with CKD who are undergoing radiographic procedures.⁵⁵¹ Although most cases of contrast-induced AKI are self-limiting, with renal function returning to normal within 7 days of the procedure, these patients occasionally (0.5–12% of cases) develop overt renal failure associated with increased morbidity and mortality. To reduce the risk of contrast-induced AKI in subjects requiring contrast-enhanced radiography, the Kidney Disease: Improving Global Outcomes (KDIGO) Clinical Practice Guidelines recommend: pre-operative hydration with i.v. isotonic fluids; the use of the minimum volume of contrast media; and the use of low-osmolar or iso-osmolar contrast media, regardless of pre-existing renal disease.⁵⁴⁷ In the post-operative phase, kidney function should be monitored by applying established AKI scoring systems to raise awareness and enable early intervention.⁵⁵²

Recommendation Table 30 — Recommendations for management of patients with renal disease undergoing non-cardiac surgery

Recommendations	Class ^a	Level ^b
In patients with renal disease requiring peri-operative contrast-enhanced radiography, balanced hydration with i.v. isotonic fluids, the use of a minimal volume of contrast media, and the use of low-osmolar or iso-osmolar contrast media should be considered. ^{547,553–555}	IIa	B
In patients with known risk factors (age >65 years, BMI >30 kg/m ² , diabetes, hypertension, hyperlipidaemia, CV disease, or smoking) undergoing intermediate- or high-risk NCS, it is recommended to screen for pre-operative renal disease by measuring serum creatinine and GFR.	I	C
If a cystatin C measurement assay is available, cystatin C measurement should be considered in patients with impaired eGFR (<45–59 mL/min/1.73 m ²) to confirm kidney disease. ⁵⁵⁶	IIa	C

BMI, body mass index; CV, cardiovascular; eGFR, estimated glomerular filtration rate; GFR, glomerular filtration rate; i.v., intravenous; NCS, non-cardiac surgery.

^aClass of recommendation.

^bLevel of evidence.

6.12. Obesity

The prevalence of people being overweight and having obesity is reaching epidemic proportions in Western countries⁵⁵⁷ and is the

second leading cause of preventable death following tobacco use.⁵⁵⁸ Obesity is defined as a body mass index (BMI) of ≥ 30 kg/m², morbid obesity as a BMI ≥ 35 kg/m², and super-morbid obesity as a BMI ≥ 50 kg/m². Obese individuals have a higher prevalence of CV risk factors and a higher risk of death,⁵⁵⁹ and are a population who are at increased risk of adverse events in the case of surgical procedures. There are specific recommendations for the pre-operative risk assessment of obese patients undergoing NCS, regardless of the presence of pre-existing cardiac conditions.⁵⁶⁰ However, while obesity accelerates the propensity for CVD, it seems that many types of CVD may have a better prognosis in the overweight population compared with their leaner counterparts, a phenomenon that is known as the 'obesity paradox'.^{561,562} Similarly, in cases of NCS, mildly obese patients present lower mortality risk compared with underweight and normal weight patients, both post-operatively and at long-term follow-up.⁵⁶³ This finding may be related to the lower prevalence of PMI in mildly obese patients undergoing NCS.⁵⁶⁴

It has been suggested that cardiorespiratory fitness (CRF), rather than BMI, should be used to assess CV risk in obese patients. While the classification based on BMI is simple, highly reproducible, and widely adopted in clinical practice, it does not reflect fat distribution and body composition. Cardiorespiratory fitness refers to the ability of the circulatory and respiratory systems to supply oxygen to skeletal muscles during sustained physical activity, which is of paramount importance, especially in patients with cardiac diseases. The primary measure of CRF is VO_2 max.⁵⁶⁵ A cohort study of nearly 10 000 patients with CAD followed for almost 15 years showed that those with relatively good CRF had favourable prognosis regardless of body composition;⁵⁶⁶ however, a lower CRF was found to be a major predictor of mortality, regardless of BMI.^{561,567} Whether specific optimization and/or treatment strategies might have a positive impact on the outcome of obese patients with pre-existing or newly diagnosed cardiac comorbidities and scheduled for NCS is a matter of ongoing controversy. Studies assessing the effect of weight loss interventions (low-energy diets with or without an exercise component) on clinical outcomes in patients undergoing NCS found inconsistent results in terms of peri-operative morbidity or mortality.^{568,569}

Recommendation Table 31 — Recommendations for management of patients with obesity undergoing non-cardiac surgery

Recommendations	Class ^a	Level ^b
It is recommended to assess cardiorespiratory fitness to estimate peri-operative CV risk in obese patients, with particular attention to those undergoing intermediate- and high-risk NCS. ^{565,570}	I	B
In patients at high risk of obesity hypoventilation syndrome, additional specialist investigation before major elective NCS should be considered. ⁵¹⁶	IIa	C

CV, cardiovascular; NCS, non-cardiac surgery.

^aClass of recommendation.

^bLevel of evidence.

6.13. Diabetes

Due to the progressive ageing of the population undergoing surgical procedures and the increasing prevalence of obesity worldwide, the prevalence of diabetes among patients undergoing NCS is expected to increase in years to come.^{4,571} Several studies have demonstrated that diabetic patients undergoing NCS have a higher prevalence of CAD than non-diabetic patients. Furthermore, patients with diabetes are more likely to have silent ischaemia because of altered neural pain pathways in the heart.⁵⁷² For this reason, patients with diabetes appear to have a greater risk of post-operative myocardial ischaemia. Different reasons exist behind the relation between DM and increased peri-operative mortality in patients undergoing NCS. First, patients with diabetes are known to have more comorbidity and/or advanced CAD at the time of intervention. Second, diabetes is a clear risk factor for stroke. Diabetes is associated with post-operative congestive HF and wound infections. Many patients with diabetes have impaired renal function. The presence or a new diagnosis of impaired glucose metabolism in patients scheduled for NCS should follow the recommendations provided for the general population in the 2019 ESC Guidelines on diabetes, pre-diabetes, and cardiovascular diseases,⁵⁷³ including increased awareness regarding possible subclinical organ damage.

The glycated haemoglobin (HbA1c) test should be performed in all patients with diabetes or impaired glucose metabolism scheduled for NCS, if this measurement has not been performed in the previous 3 months. There is evidence to support that pre-admission optimal treatment of hyperglycaemia in patients scheduled for elective NCS is effective in reducing the post-operative risk of CV events, including MI, stroke, and progression of HF.⁵⁷⁴ In contrast, no clear association has been shown between intra-operative blood glucose levels and the subsequent risk of surgical site infection, MI, stroke, and death in patients undergoing NCS.⁵⁷⁵ The risk of acidosis associated with metformin use is also debated.⁵⁷⁶ Nevertheless, repeated blood glucose monitoring on the day of surgery is recommended, with a general consensus to maintain peri-operative glucose levels <10.0 mmol/L without causing hypoglycaemia (target level 5.6–10.0 mmol/L). This can be achieved either with subcutaneous doses of rapid-acting insulin analogues or with i.v. insulin.⁵⁷⁷ Handling of SGLT2 inhibitors in relation to surgery has been discussed in [Section 5.2](#).

Recommendation Table 32 — Recommendations for management of patients with diabetes mellitus undergoing non-cardiac surgery

Recommendations	Class ^a	Level ^b
In patients with diabetes or disturbed glucose metabolism, a pre-operative HbA1c test is recommended, if this measurement has been not performed in the previous 3 months. In case of HbA1c $\geq 8.5\%$ (≥ 69 mmol/mol), elective NCS should be postponed, if safe and practical. ^{578–581}	I	B

Continued

A pre-operative assessment for concomitant cardiac conditions (see [Sections 3](#) and [4](#)) is recommended in patients with diabetes with suspected or known CAD, and those with autonomic neuropathy, retinopathy, or renal disease and scheduled to undergo intermediate- or high-risk NCS.

^bLevel of evidence.

6.14. Cancer

Due to their generally older age, cancer patients have a high prevalence of CV risk factors and CVD, being a population at increased risk of adverse events in cases of NCS. It is therefore important to optimize treatment of CV risk factors and known CVD before NCS, following the general and disease-specific recommendations provided in other sections of these guidelines. Furthermore, NCS may be particularly challenging in cancer patients because of previous administration of potentially cardiotoxic chemotherapy or fibrosis due to previous radiation. For example, the widely used anthracyclines have a dose-dependent relation with the incidence of HF and the use of trastuzumab can lead to important cardiotoxicity and should be taken into account in the pre-operative assessment. Furthermore, radiation therapy to areas that included the heart may lead to premature CAD and VHD; previous thoracic radiotherapy may predispose younger patients to heart disease who would otherwise not have an elevated risk. Post-operative AF is frequently observed in patients undergoing cancer surgery, with the highest incidence reported for lung surgery. Patients with cancer are at elevated risk of thrombosis due to both the disease itself and patient- and treatment-related factors. In a small study of patients undergoing planned open surgery for abdominal or pelvic cancer, enoxaparin prophylaxis for 4 weeks compared with 1 week reduced the incidence of thrombosis (4.8% in the enoxaparin group vs. 12.0% in the placebo group; $P = 0.02$).⁵⁸² Although later studies have shown somewhat conflicting results, the consensus is to recommend extending thromboprophylaxis after major abdominal and/or pelvic surgery for cancer to 4–5 weeks, with preferred use of LMWH.⁵⁸³ A summary of patient-related and cancer therapy-related factors that could influence peri-operative risk is shown in [Table 15](#). Further information is available in the 2022 ESC Guidelines on cardio-oncology.⁵⁸⁴

6.15. Coronavirus disease 2019

Coronavirus disease 2019 (COVID-19) is an infectious disease caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). In a recent observational study, among 140 231 patients scheduled for NCS, 2.2% of patients had a pre-operative diagnosis of SARS-CoV-2 infection.⁵⁸⁵ Patients undergoing surgery with peri-operative or recent SARS-CoV-2 appear to be at increased risk of post-operative VTE and mortality compared with patients with no history of SARS-CoV-2 infection.⁵⁸⁶ Furthermore, the possible myocardial injury associated with COVID-19 infection might increase the

Table 15 Factors that could influence peri-operative risk during cancer surgery and preventive strategies

	Factors that could influence peri-operative risk during cancer surgery	Preventive strategies
• Patient-related factors	<ul style="list-style-type: none"> • Lifestyle risk factors—smoking, obesity, sedentary lifestyle • Poorly controlled CV risk factors—hypertension, diabetes • Pre-existing CVD, including cancer therapy-related cardiovascular toxicity • Cardiac medication increasing peri-operative bleeding risk (e.g. antiplatelets and anticoagulants) • Historical primary malignancy • Current cancer type, stage, and location • Arrhythmias (due to myocardial cancer invasion, induced QT-prolongation, AF, or imbalance of autonomic nervous system) 	<ul style="list-style-type: none"> • Optimal management of CV risk factors and CVD • Optimize preventive strategies with respect to VTE and arterial thromboembolic events • ECG monitoring for arrhythmias • Correction of all proarrhythmic conditions
• Neoadjuvant cancer therapy	<ul style="list-style-type: none"> • Previous cardiotoxic cancer treatments (especially anthracycline chemotherapy and/or trastuzumab; immune checkpoint inhibitors, VEGFi, fluoropyrimidine and thoracic radiotherapy) • Cancer treatments increasing peri-operative bleeding risk (e.g. antiangiogenics, BTKi) • Cancer treatments increasing risk of arrhythmias 	<ul style="list-style-type: none"> • Ensure optimal CV monitoring of neoadjuvant therapy • Optimize preventive strategies with respect to VTE and arterial thromboembolic events

intrinsic peri-operative risk of adverse cardiac events associated with surgical procedures.^{587,588}

To date, there is no specific CV screening to be performed after COVID-19 infection in patients scheduled for NCS. The pre-operative evaluation of CV risk associated with NCS in this specific subset of patients should incorporate, beyond the general risk assessment outlined in these guidelines, the severity of COVID-19 disease, history of CV complications during COVID-19 infection, and functional capacity after recovery. This information is deemed of importance to further optimize timing of surgery and the treatment of COVID-19-associated cardiovascular conditions affecting the peri-operative risk of NCS.⁵⁸⁹

The optimal timing of NCS in patients with a history of COVID-19 infection is largely unknown. Generally, elective NCS should be postponed until complete recovery and optimization of coexisting comorbidities. Registry data of patients undergoing NCS after COVID-19 infection report increased risks of mortality and morbidity up to 7 weeks post-COVID diagnosis.⁵⁸⁶ Another study has reported greater risk of post-operative complications up to 8 weeks post-diagnosis.⁵⁹⁰ However, it should be noted that almost all available data come from study periods with zero to low prevalence of vaccination, and no robust data exist on patients recovering from the more recent Delta and Omicron variants.

A joint statement on elective surgery and anaesthesia for patients after COVID-19 infection from the American Society of Anaesthesiologists and Anaesthesia Patient Safety Foundation⁵⁹¹ suggests delaying elective surgery for 7 weeks after a SARS-CoV-2 infection in unvaccinated patients who are asymptomatic at the

time of surgery. The clinical course of COVID-19 infection, presence and intensity of cardiopulmonary symptoms during the acute and late phases, and pre-existing comorbidities should be taken into consideration. In addition, persistence of COVID-19 symptoms—such as fatigue, shortness of breath, and chest discomfort—should be given attention, as this condition is associated with higher post-operative mortality independent of the timing of COVID-19 diagnosis.^{588,589} The evidence is currently insufficient to make recommendations for those who become infected after vaccination.

7. Peri-operative monitoring and anaesthesia

7.1. Peri-operative monitoring

Despite the absence of prospective RCTs investigating the prognostic relevance of peri-operative monitoring, previous evidence clearly indicates that the routine use of monitoring improves safety of surgical procedures. Mandatory intra-operative monitoring of the CV and respiratory systems, temperature, neuromuscular transmission, and depth of anaesthesia is recommended.^{592,593}

Routine CV monitoring includes ECG, automated non-invasive BP measurement at regular intervals, and peripheral oxygen saturation with pulse oximetry. Near-infrared spectroscopy has recently been introduced to assess regional tissue perfusion and oxygenation. In selected cases, more invasive monitoring techniques can be applied such as continuous arterial BP measurement via an arterial catheter and monitoring of cardiac output. Mean arterial pressure and heart

rate remain stable, even with variation of up to 30% of total blood volume.⁵⁹⁴ Right heart catheterization can be used to continuously measure central venous pressure and/or pulmonary artery pressure, pulmonary artery wedge pressure (as a reflection of LV diastolic pressure), and cardiac output. However, these are static variables that do not reliably reflect the CV filling status, and have been shown to accurately guide fluid therapy in 50% of patients.⁵⁹⁵

While routine use of pulmonary catheterization is discouraged during NCS, using dynamic variables, such as stroke volume variation or pulse pressure variation, has become the gold standard. In addition, TEE is increasingly being used as an intra-operative monitoring technique in major surgery in cardiac compromised patients and during cardiac surgery. Decisions on the extent of peri-operative monitoring and implementation of specific strategies during NCS should always be based on an individual patient-directed assessment, taking into consideration the severity of surgery and the patient's physical condition. Basic peri-operative monitoring of the respiratory system consists of pulse oximetry and capnography; both methods are non-invasive and easily applicable. Pulse oximetry enables *in vivo* measurement of arterial oxygen saturation, and capnometry measures end-tidal carbon dioxide concentration during inspiration and expiration; these monitors also provide information about the global haemodynamic status.

Patients, independent of the anaesthetic technique and information provided by the different monitoring systems, must be regularly controlled.⁵⁹⁶ In addition, blood loss and urine output should be checked, when appropriate, and overall clinical status.⁵⁹⁷ Special attention is required for the activation and setting of audible alarms, as inadequate use or failure to respond to intra-operative alarms may result in patient hazard and undesirable outcomes.⁵⁹⁸

7.2. Anaesthesia

The decision on the optimal peri-operative strategy should be based on close exchange of clinical information between anaesthesiologists, cardiologists, surgeons, and other relevant specialists. In addition, it is mandatory that any proposed strategy is presented to and discussed with the patient. An informed discussion with the patient describing the planned patient pathway and expectations during the pre-, peri-, and post-operative phases of care, and what to expect from staff and surroundings, should be given using a clear, concise, and simple description. The ESA published Pre-operative evaluation of adults undergoing elective noncardiac surgery: updated Guideline from the European Society of Anaesthesiology in 2018.⁵⁶⁰ This current section focuses on issues that are specifically important to patients with CV risk factors and diseases, taking into account the most recent developments in peri-operative management of these patients.

7.2.1. Intra-operative haemodynamics

Most anaesthetic techniques reduce sympathetic tone, leading to a decrease in venous return due to increased compliance of the venous system, vasodilatation, and decreased BP. Therefore, maintenance of adequate organ flow and perfusion pressure is of key importance in anaesthesiological management, especially in the CV-compromised patient. The importance of keeping stable peri-operative haemodynamics has been recognized for many years.⁵⁹⁹

In the past few years, several studies have focused on the relationship between intra-operative hypotension and post-operative

patient outcome. A recent systematic review identified 42 studies looking at associations between various absolute and relative intra-operative hypotension definitions and post-operative adverse outcomes after NCS.²¹⁴ The reported associations suggest that organ injury (myocardial injury, stroke, AKI) might occur when the mean arterial pressure decreases to <80 mmHg for ≥ 10 min, and that this risk increases with BP becoming progressively lower. However, most of the included studies had a retrospective observational design with a large variability in patient characteristics. In addition, the definitions of intra-operative hypotension varied widely across included studies. A recent study on the incidence of intra-operative hypotension as a function of the chosen cut-off definition described 48 different definitions of intra-operative hypotension. When applying these definitions to a cohort of 15 509 consecutive adult patients undergoing NCS under general anaesthesia, any episode of systolic BP <80 mmHg was found in 41% of the patients, and 93% of the patients had at least one episode of systolic BP >20% below baseline. The relation between threshold values from the literature and incidence of intra-operative hypotension showed a sigmoidal shaped cumulative incidence curve, with intra-operative hypotension occurrence frequencies varying from 5–99%.⁶⁰⁰ It seems that no universal target BP to define intra-operative hypotension can currently be defined. In addition, in studies on intra-operative hypotension, both the threshold to define hypotension and the method chosen to model intra-operative hypotension affected the association of intra-operative hypotension with outcome.⁶⁰¹ As a consequence, different studies on intra-operative hypotension are uncomparable and clinical conclusions on reported results remain hazardous. A recent expert consensus statement concluded that intra-operative mean arterial pressures <60–70 mmHg are associated with myocardial injury, AKI, and death. These complications are a function of hypotension severity and duration.⁶⁰² It remains to be established whether correction of intra-operative hypotension is also associated with improved post-operative outcome. To date, only one study has specifically addressed the question of whether an individualized BP management strategy reduces post-operative complications in a multicentre RCT including 292 patients. An individualized management strategy of targeting a systolic BP within 10% of the patient's normal resting value resulted in significantly lower rates of post-operative organ dysfunction compared with standard practice (38.1% vs. 51.7%, respectively).⁵²⁸ These findings support the benefits of personalizing care, especially in surgical patients at high-risk of cardiac complications. It is important to underscore the importance of a physiopathological approach in understanding the underlying mechanisms of intra-operative hypotension, taking into account the extent and severity of the patient's comorbidities; only then will a tailored treatment targeting the cause of intra-operative hypotension be possible (Figure 16).

The severity of intra-operative hypotension is defined both by the threshold decrease from baseline and the duration of the hypotensive episode. The underlying mechanisms for intra-operative hypotension need to be identified: sympathicolysis with vasodilation, hypovolaemia, or other more complex causes such as peri-operative myocardial failure. Once the underlying mechanisms are identified, a targeted therapeutic strategy can be applied. This includes considering whether administration of specific chronic vasoactive medication such as ACEIs or ARBs should be interrupted 24 h prior to surgery.²¹⁶

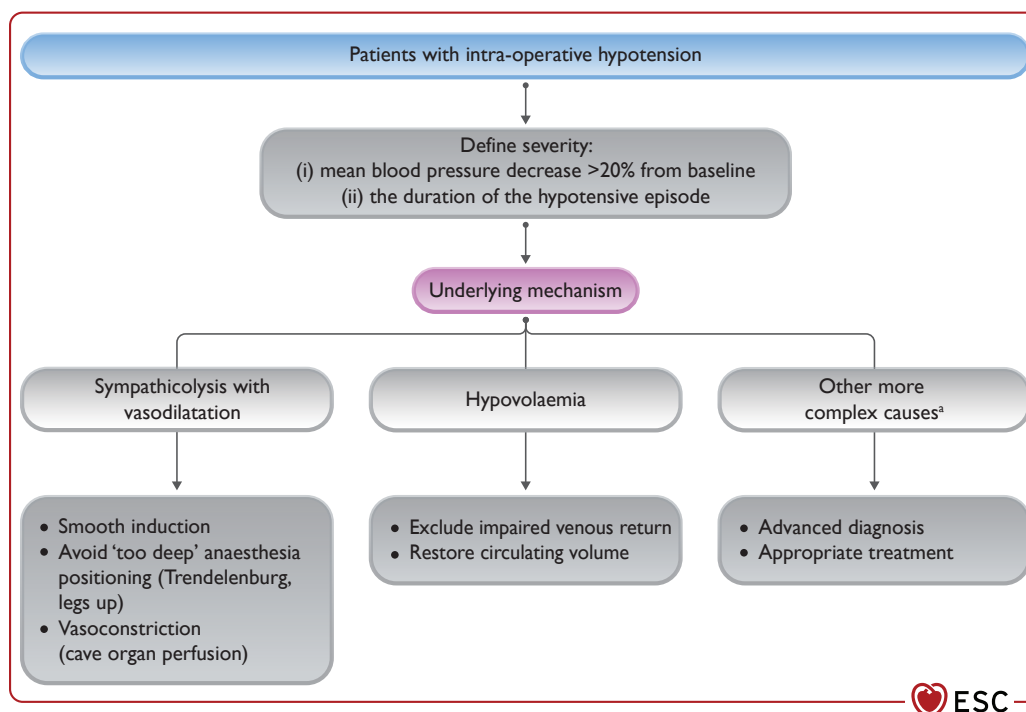

Figure 16 Pathophysiological approach to address intra-operative hypotension. ^aE.g. peri-operative myocardial failure.

A detailed analysis of the strategies for the different chronic CV medication is discussed in [Section 5](#). Of note, post-operative outcome is not only negatively influenced by the occurrence of intra-operative hypotension, but also by hypotensive events during the initial four post-operative days.⁶⁰³ For adult non-cardiac surgical patients, there is insufficient evidence to recommend a general upper limit of arterial pressure at which therapy should be initiated, although pressures >160 mmHg have been associated with myocardial injury and MI.⁶⁰²

Intra-operative tachycardia may adversely affect the myocardial oxygen balance and thus result in peri-operative myocardial injury. A retrospective analysis of 41 140 patients found that a heart rate ≥ 90 b.p.m. was associated with an increased risk of myocardial injury.⁶⁰⁴ These findings were similar to observations in the Vascular Events in Noncardiac Surgery Patients Cohort Evaluation (VISION) trial.⁶⁰⁵ An analysis of high-risk surgical patients found that an HR >87 b.p.m., recorded at rest before pre-operative cardiopulmonary exercise testing, was strongly associated with distinct CV phenotypes, which may explain the unintended, adverse consequences of non-personalized treatments aimed at reducing intra-operative tachycardia in isolation from other haemodynamic factors.⁶⁰⁶ Finally, a recent study evaluated the association between intra-operative tachycardia and a composite of post-operative myocardial injury and all-cause mortality. The major finding of this study was the lack of an association between intra-operative heart rate >90 b.p.m. and the composite outcome; HR >80 b.p.m. or >100 b.p.m. were also not associated with the composite outcome.⁶⁰⁷ Taken together, the assumed association between intra-operative tachycardia and adverse peri-operative outcome remains a subject of ongoing controversy. However, it seems

advisable to consider intra-operative tachycardia as an indicator of haemodynamic impairment.

7.2.2. Choice of anaesthetic agent

The choice of the anaesthetic agent has been considered to be of little importance in terms of patient outcome, provided that vital functions are adequately supported. Evidence from surgical myocardial revascularization studies indicates that a volatile vs. i.v. anaesthetic regimen is associated with less post-operative troponin release without impact on clinical outcomes.^{599,608} A recent large multicentre randomized trial found a neutral effect on 12 month mortality associated with volatile vs. i.v. anaesthetic regimen.⁶⁰⁹ In NCS, incidence of post-operative cardiac events is not influenced by the choice of a volatile or an i.v. anaesthetic regimen.⁶¹⁰

7.3. Locoregional techniques

The analgesic effects of neuraxial analgesia are well-established. The main peri-operative indications for epidural analgesia include major open abdominal surgery and thoracotomy. Possible additional benefits of epidural analgesia, such as accelerated recovery and decreased post-operative complications, remain a matter of debate.^{611,612}

Neuraxial analgesia may induce sympathetic blockade. When reaching the thoracic dermatome level 4, a reduction in cardiac sympathetic drive may occur, with subsequent reduction in myocardial contractility, heart rate, and change in cardiac loading conditions. There are no studies specifically investigating the changes in outcomes related to neuraxial anaesthetic techniques in patients with cardiac disease. Cardiac patients often take various types of drugs that interfere with coagulation; therefore, care should be taken to ensure sufficient coagulation ability when neuraxial blocks are applied.⁶¹³

Current research is focusing on alternatives for neuraxial analgesia with similar effects on peri-operative pain control in patients with cardiac comorbidities undergoing NCS; these include alternative analgesic techniques such as i.v. analgesia, continuous wound infiltration, paravertebral bloc, and selective nerve blocks.

7.4. Peri-operative goal-directed haemodynamic therapy

Goal-directed therapy aims to optimize CV performance, in order to achieve normal or even supranormal oxygen delivery to tissues, by optimizing pre-load and inotropic function using pre-defined haemodynamic targets. In contrast to clinical signs or arterial pressure-orientated standard therapy, goal-directed therapy is based on flow or fluid responsiveness of haemodynamic variables, such as stroke volume, response to fluid challenges, stroke volume or pulse pressure variation, or similar optimization of cardiac output. Goal-directed therapy was initially based on the use of a pulmonary artery catheter. Less-invasive techniques have recently been developed, including: transoesophageal Doppler, transpulmonary dilution techniques, and advanced pressure waveform analysis. Early goal-directed fluid therapy—in the right patient cohort and with a clearly defined protocol—has been shown to decrease post-operative mortality and morbidity.^{614–618}

7.5. Post-operative management

Several studies have demonstrated that it is possible to stratify the risk of post-operative complications and mortality with a simple surgical Apgar score. This post-event stratification might enable patients to be redirected to higher-intensity care units. The importance of such risk stratification is underscored by the results of the EuSOS group. In this 7 day cohort study, 46 539 consecutive adult NCS patients in 498 hospitals across 28 European nations were included: 1855 patients (4%) died before hospital discharge and 1358 (73%) of those patients were not admitted to critical care at any stage after surgery.⁷ This concept of failure-to-rescue has gained a lot of attention in peri-operative medicine in the last few years and strategies have been proposed to address this issue.^{619–622}

Severe post-operative pain occurs in 5–10% of patients, increases sympathetic drive, and delays recovery.^{623,624} A recent study demonstrated that time-weighted average pain scores within 72 h after surgery were significantly associated with myocardial injury in patients undergoing NCS;⁶²⁵ this finding underscores the importance of effective post-operative analgesia to reduce post-operative CV risk.

The place of non-steroidal anti-inflammatory drugs (NSAIDs) in the treatment of post-operative pain in cardiac patients undergoing NCS is a point of debate. Diclofenac has been shown to carry the highest CV risk of any of the non-selective NSAIDs.^{626,627} The CV risk of ibuprofen seems to be comparable with that of celecoxib.⁶²⁸ Naproxen has a better CV safety profile than diclofenac and ibuprofen.^{629,630} One randomized trial found that parecoxib and valdecoxib did not increase thromboembolic events in patients undergoing NCS. A meta-analysis of 32 randomized trials did not find an increased CV risk when comparing parecoxib/valdecoxib with placebo,⁶³¹ and a single-centre observational study with >10 000 patients undergoing arthroplasty found no association between

NSAID use and post-operative MI.⁶³² In contrast, another meta-analysis of three randomized trials including 2604 major surgery patients detected a 2.3-fold increase in MACEs in the group with COX-2 inhibitors. In a position paper, The ESC Working Group on Cardiovascular Pharmacotherapy advises that non-aspirin NSAIDs should generally not be used in patients with established or at high risk of CVD.⁶³³

Recommendation Table 33 — Recommendations for peri-operative monitoring and anaesthesia

Recommendations	Class ^a	Level ^b
In order to preserve optimal CV stability, it is recommended to apply goal-directed haemodynamic therapy in patients undergoing high-risk NCS. ^{614–618}	I	A
It is recommended to avoid post-operative acute pain. ⁶¹⁴	I	B
In order to minimize the risk of post-operative organ dysfunction, it is recommended to avoid an intra-operative mean arterial pressure decrease of >20% from baseline values or <60–70 mmHg for ≥10 min. ^{214,600–602,634}	I	B
Non-aspirin NSAIDs are not recommended as first-line analgesics in patients with established or high risk of CVD. ^{633,635}	III	B

8. Peri-operative cardiovascular complications

Specific challenges apply to detecting CV complications that occur peri-operatively. First, due to anaesthesia and analgesia, PMI, which is the most common CV complication, is largely asymptomatic in ~90% of patients and is therefore missed in routine clinical practice in the absence of surveillance for PMI.^{41,101,111,413,636–641} Second, post-operative pain, nausea, surgical wounds, and drains may interfere with the early identification of acute cardiac disorders, such as PMI, Takotsubo syndrome, tachyarrhythmias, and acute HF. Third, cardiologists are usually not directly involved in post-operative care; therefore, the early detection and early treatment of cardiac complications is performed by non-cardiologists, sometimes with little training in the early detection of acute cardiac disorders. Given the relatively high prevalence of cardiac complications, their high morbidity and mortality, and the availability of effective therapy, high awareness combined with surveillance for PMI in high-risk patients (known CAD, PAD, insulin-dependent DM, or symptoms suggestive of cardiac disorders) undergoing intermediate- or high-risk NCS is recommended to overcome

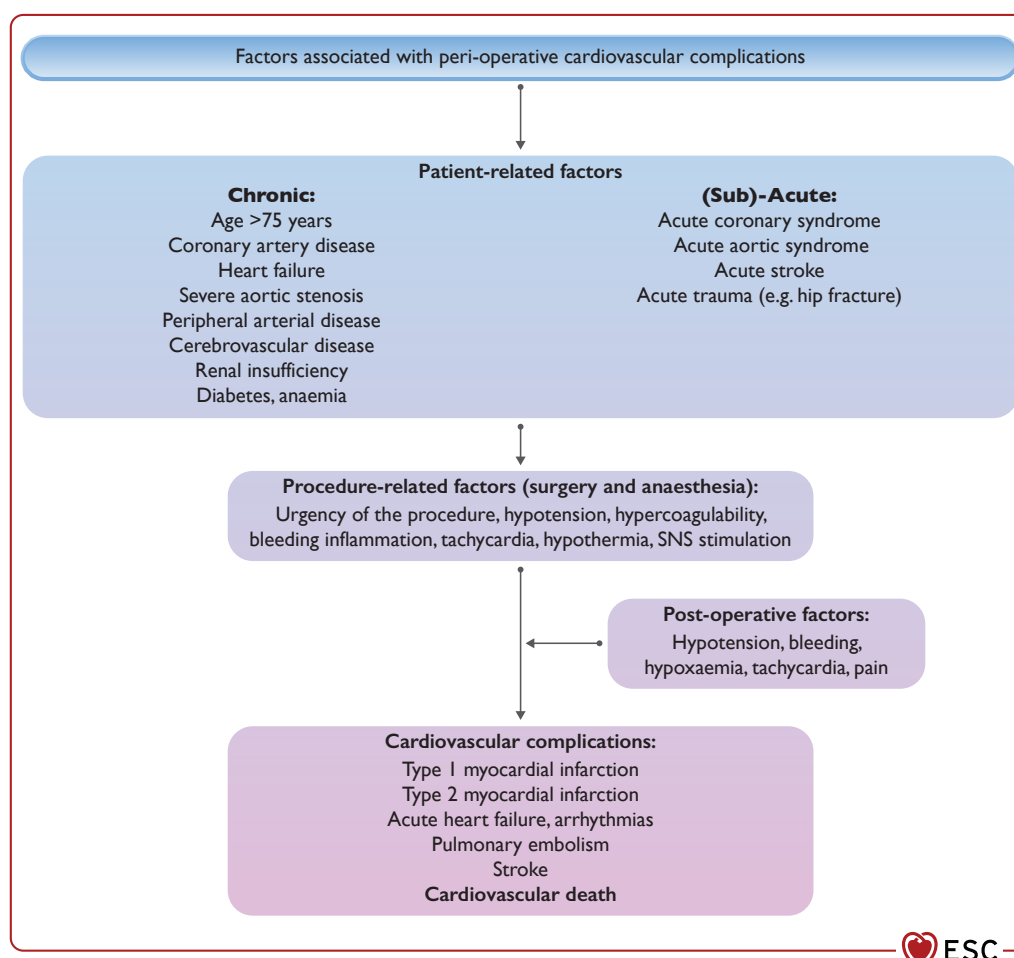

Figure 17 Factors associated with peri-operative cardiovascular complications. SNS, sympathetic nervous system.

these challenges.^{41,101,109–111,118,413,636–639,642,643} All measures need to be carefully aligned with the responsible surgeon.

Chronic cardiac disorders, such as CAD, seem to provide a substrate for cardiac complications during and after surgery.^{41,413,636,637} Several related chronic conditions (e.g. diabetes and renal insufficiency), which are likely to be surrogates for undiagnosed cardiac disease, are also strongly associated with peri-operative cardiac complications (Figure 17).^{41,413,636,637}

Acute conditions such as trauma, surgery, and anaesthesia itself induce activation of the sympathetic nervous system, inflammation, stress, hypercoagulable, and catabolic states, all of which may trigger cardiac complications.^{41,413,636,637} While the risk of CV complications after NCS is highest in the immediate peri-operative period, it seems to remain increased for a prolonged ‘vulnerable period’ of 3–5 months.⁸

8.1. Peri-operative myocardial infarction/injury

Peri-operative MI (PMI) is defined as acute cardiomyocyte injury (post-operative hs-cTn T/I release) with or without accompanying symptoms, and with or without ECG or imaging evidence of acute myocardial ischaemia. Peri-operative MI can only be reliably and

rapidly detected using PMI surveillance with hs-cTn T/I measurements before and serially after surgery (e.g. 24 and 48 h post-operatively). In the BASEL-PMI study, circa 15% of patients with pre-existing CAD/PAD or aged >65 years undergoing major NCS developed PMI.⁸ As most PMI occurs during the operation itself or in the immediate post-operative period, during which high doses of anaesthetics and/or analgesics are required, ~90% of patients with PMI do not report typical symptoms and are therefore missed in routine clinical practice.^{41,101,111,413,636–639} This is of major concern, as the mortality risk associated with PMI is also high in patients without symptoms.^{41,101,111,413,636–639} Similarly, the mortality risk associated with PMI is high in patients without additional ECG and/or imaging evidence of myocardial ischaemia.^{8,41,101,109–111,118,413,564,636–639,641} Overall, 30 day mortality in patients developing PMI is ~10%.^{8,41,101,109–111,118,413,564,636–639,641} No single intervention has yet been proven to be unequivocally beneficial in the prevention of PMI.^{185,644}

It is important to highlight that PMI is not a homogenous disease. Several different pathophysiologies and clinical phenotypes may underlie PMI (Figure 18). At least one additional criterion (ischaemic pain; ischaemic ECG changes; imaging evidence of new loss of viable myocardium, or new regional wall motion abnormality in a pattern consistent with an ischaemic aetiology; and thrombus in coronary

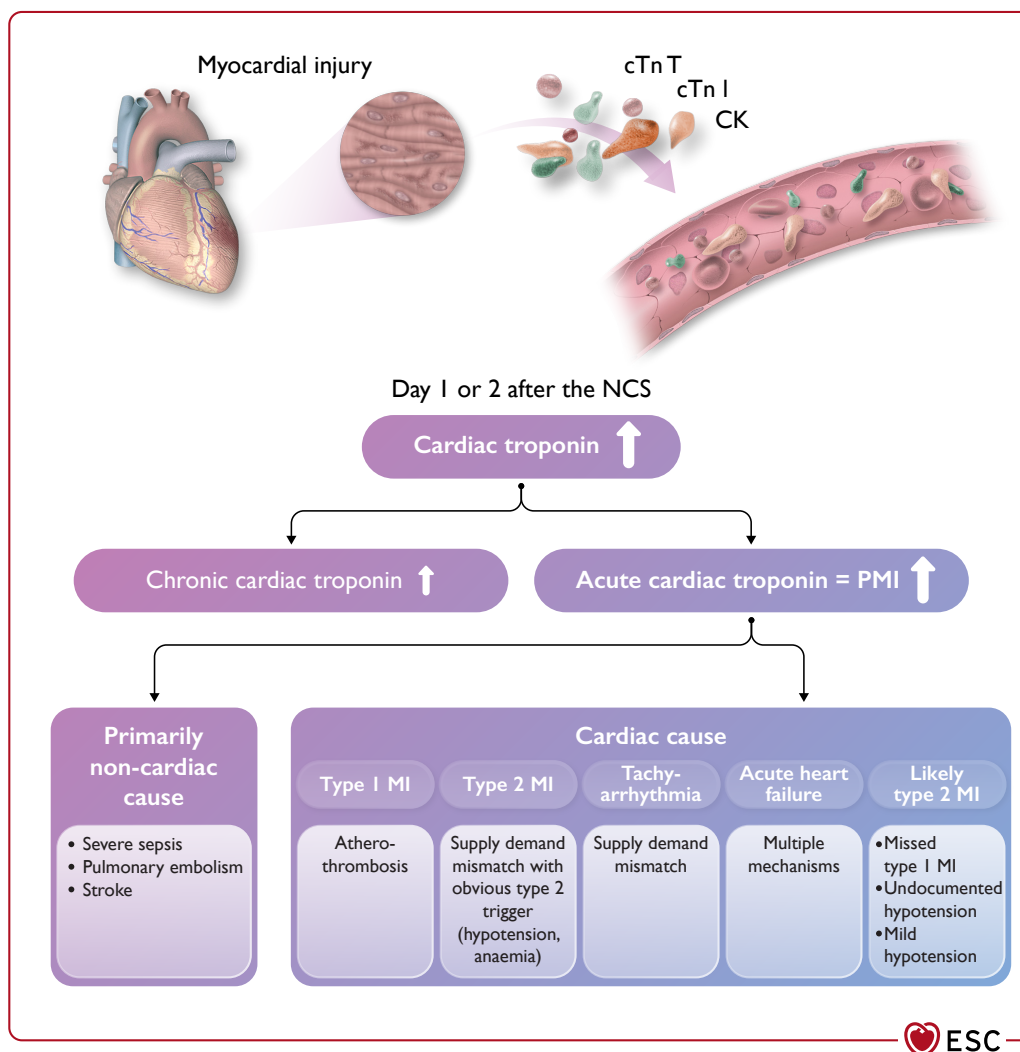

Figure 18 Differential diagnosis of elevated post-operative cardiac troponin concentrations. CK, creatinine kinase; cTn I, cardiac troponin I; cTn T, cardiac troponin T; MI, myocardial infarction; PMI, peri-operative myocardial infarction/injury. Please be aware that the accuracy of physicians' judgement in the classification of type-1 vs. type-2 MI in the peri-operative setting may be lower vs. the non-operative setting.⁶⁴⁷

angiography) is required for patients with PMI to also meet the definition of peri-operative myocardial infarction, according to the fourth universal definition.⁶⁴³ Because it is often initially unclear whether the patient will end up fulfilling the criteria for peri-operative myocardial infarction, the broad term PMI is preferred in the initial assessment. In order to properly interpret the aetiology of elevated post-operative hs-cTn T/I concentrations, a baseline pre-operative concentration is necessary to determine whether the increase is acute or chronic (see Section 4).⁶⁴³ To identify the underlying pathophysiology and define causal therapy, systematic work-up and early differentiation of primarily non-cardiac causes (e.g. severe sepsis, PE) vs. the different cardiac causes—including type-1 MI, type-2 MI, tachyarrhythmia, and acute HF—is of major importance (Figures 18 and 19). Transthoracic echocardiography is helpful in the work-up of most patients with PMI.

The term myocardial injury following NCS (MINS) has been used for a selected subset of patients with cardiac PMI, in whom cardiomyocyte injury was deemed most likely due to CAD with myocardial

ischaemia (i.e. secondary to supply–demand mismatch or thrombosis), in the absence of an atypical surgical physiological stress, and no evidence of a cardiac non-CAD aetiology, e.g. rapid AF, acute HF).^{101,109,638,641,642,645,646} In approximately half of all patients with PMI, the underlying pathophysiology cannot be reliably ascertained based on the commonly available documentation and is assumed to be likely type-2 MI due to undocumented or relative hypotension, but may also include missed type-1 MI, or missed PE in cases in which CT angiography has not yet been performed post-operatively.^{110,647} It is therefore important to highlight that PMI surveillance also facilitates the detection of primarily non-cardiac disorders with immediate therapeutic consequences, such as PE, that would otherwise have been missed.

The prevalence of PMI depends on patient-related, procedural-related, and post-operative factors, and the required minimum extent of acute myocardial injury, quantified by absolute increase in hs-cTn T/I (e.g. the 99th percentile ULN) above the pre-operative hs-cTn T/I concentration.^{8,41,101,109–111,118,413,564,636–639,641,648}

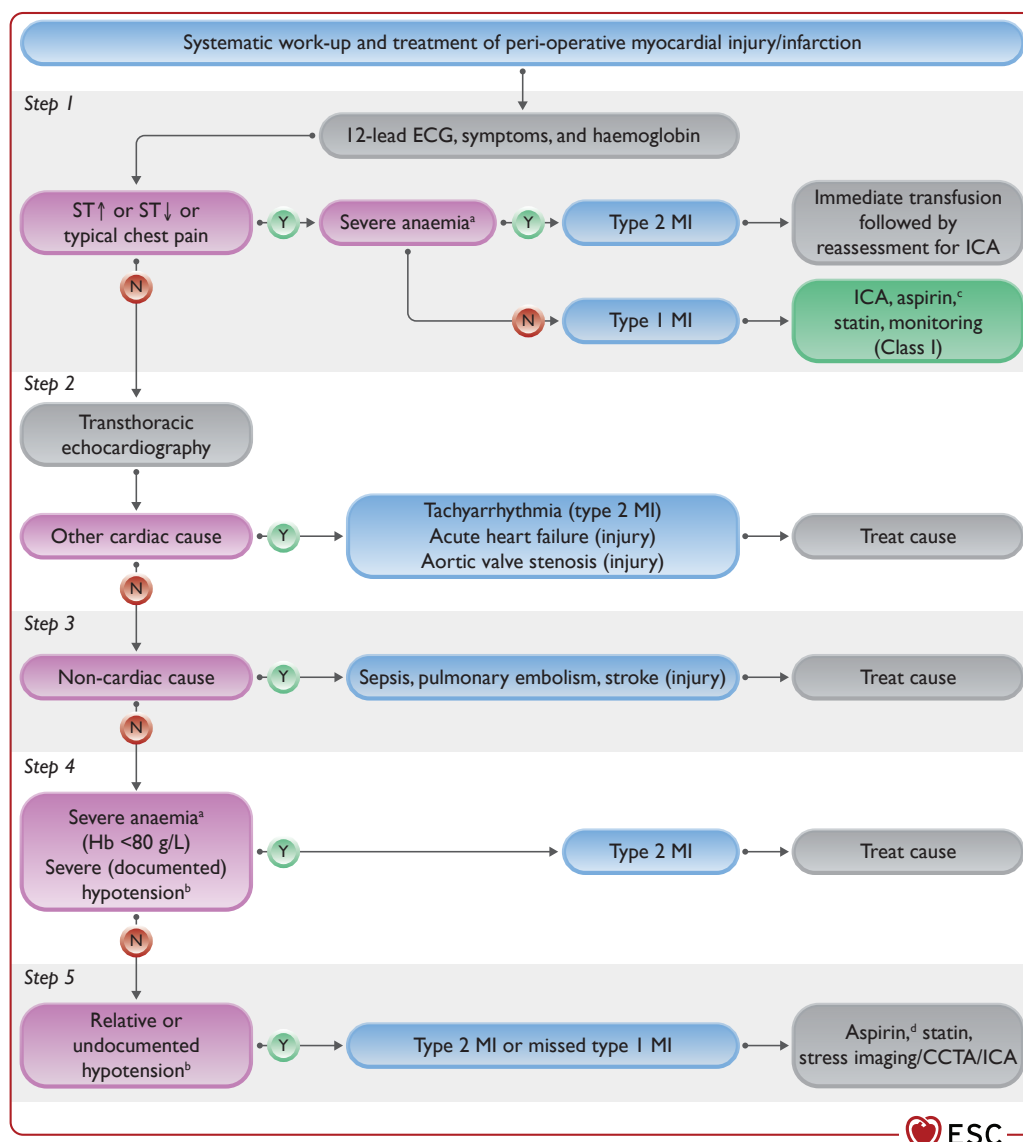

Figure 19 Systematic work-up (aetiology) and therapy of peri-operative myocardial infarction/injury. CCTA, coronary computed tomography angiography; ECG, electrocardiogram; Hb, haemoglobin; ICA, invasive coronary angiography; MI, myocardial infarction; N, no; ST, ST-segment. Y, yes; Most patients with type-2 MI and silent type-1 MI should be scheduled for stress imaging or CCTA/ICA as outpatients after discharge, depending on symptoms prior to or after surgery and known CAD. ^aOr active bleeding. ^bOr other type-2 MI trigger such as hypoxaemia, tachycardia, hypertension. ^cDual antiplatelet therapy after coronary stenting. ^dPossibly in combination with dabigatran 110 mg *b.i.d.*

An absolute increase in more than the ULN above pre-operative concentrations has consistently been shown to be associated with a relevant increase in 30 day and long-term mortality, and other non-fatal post-operative cardiac complications, and can easily be determined for each hs-cTn T/I assay. This threshold is therefore recommended for clinical use.^{8,41,101,109–111,118,413,564,636–639,641,648} However, further studies are warranted regarding optimal thresholds. Emerging data suggest that surveillance for PMI is cost-effective.^{117,119}

Identification of the most likely pathophysiology is critical for selection of the most appropriate therapy. Evidence from a large single-centre retrospective cohort suggests that involvement of a cardiologist in the work-up and therapy of these patients was associated with

lower mortality.⁶⁴⁹ Mortality substantially differs among the different phenotypes: 30 day all-cause mortality and the composite of 30 day CV death, life-threatening arrhythmia, acute MI occurring after day 3, and cardiac decompensation are highest in patients with acute HF and primarily extra-cardiac PMI, such as severe sepsis or PE, intermediate for type-1 MI and tachyarrhythmias, and modestly elevated in likely type-2 MI.¹¹⁰ Type-2 MI patients are usually treated as for type-1 MI, although the evidence for this is limited.

In a randomized, placebo-controlled trial, 1754 patients (mean age 70 years) who had developed MINS after NCS (mainly orthopaedic, general, and vascular surgery) were randomly assigned (1:1) to receive dabigatran 110 mg orally *b.i.d.* or matched placebo within 35 days of MINS;⁶⁵⁰ 60% of patients were already on aspirin or a

P2Y₁₂ inhibitor. The median peak measured hs-cTn concentration associated with the diagnosis of MINS was 82 ng/L. More than 90% of MINS events occurred without a clinical symptom or sign of cardiac ischaemia. Dabigatran/placebo was initiated a median of 6 days after the operation and the average time on study drug was ~9 months. Among patients with MINS randomly assigned to receive dabigatran (*n* = 877) or placebo (*n* = 877), the composite primary efficacy outcome of a major vascular complication—including vascular mortality, MI, non-haemorrhagic stroke, peripheral arterial thrombosis, amputation, and symptomatic VTE—occurred in fewer patients randomized to dabigatran than placebo (97 [11%] of 877 patients assigned to dabigatran vs. 133 [15%] of 877 patients assigned to placebo; HR, 0.72; 95% CI, 0.55–0.93; *P* = 0.0115). There was no increase in major bleeding. Based on these data, in patients with MINS and at low risk of bleeding, initiation of dabigatran 110 mg orally *b.i.d.* may be considered about 1 week after NCS.

8.2. Spontaneous myocardial infarction (after day 2)

The incidence of post-operative spontaneous MI after day 2 seems to be about 0.5% within 30 days, and 1–2% within 365 days for patients undergoing major NCS with established CAD, PAD, or aged >65 years.⁸ In the immediate post-operative period (<5 days), bleeding is a major concern and limits the use of antiplatelet and anticoagulant therapy, depending on the site and extent of surgery. Otherwise, the same principles as for MI therapy should generally be applied following the recommendations of speciality guidelines.^{98,171}

8.3. Takotsubo syndrome

The incidence of peri-operative Takotsubo syndrome remains unknown, as none of the studies with PMI screening used echocardiography in all patients during PMI work-up. Increased awareness in the non-operative setting has led to a substantial increase in the detection of Takotsubo syndrome, and the use of TTE in the work-up of PMI is strongly encouraged. Anecdotal evidence suggests that it is likely that the incidence is also higher than expected in the peri-operative setting.^{8,41,101,109–111,118,413,564,636–639,641,644}

8.4. Acute heart failure

The incidence of post-operative acute HF seems to be 1–2% within 30 days and 4–6% within 365 days in patients with established CAD, PAD, or aged >65 years undergoing major NCS.⁸ Pre-existing diagnosed or undiagnosed chronic HF and volume loading in the peri-operative and post-operative periods are important contributors. In the absence of studies specifically investigating acute HF post-operatively, the general principles of acute HF diagnostic work-up and therapy should be applied.⁶⁵¹

8.5. Venous thromboembolism

The incidence of VTE in the peri-operative phase is currently unknown and likely underreported due to the lack of systematic screening methods and the limited validity of diagnostic tools (e.g. D-dimer, typical pain symptoms) in this setting. It is associated with high peri-operative mortality (~17%).³²² Risk factors for post-operative VTE/PE include type of surgery (e.g. high-risk hip arthroplasty, open prostatectomy, open surgery for malignancy), acute

renal insufficiency, MI, and post-operative infection.³²² Stratification of the extent of embolism (e.g. massive, submassive, and subsegmental; high risk, intermediate high/low risk, and low risk) is important to predict mortality and guide therapeutic strategy.⁶⁵² Pulmonary embolism should be suspected in patients with PMI without a clear cause. Close haemodynamic monitoring and monitoring of RV function (echocardiography, CT) is essential to determine which PE patients require aggressive therapy. There is currently a lack of evidence regarding adequate antithrombotic therapy in patients with post-operative PE, since recent major surgery or trauma was a contraindication in previous trials of thrombolytic or anticoagulant therapy.⁶⁵³ Small case series support the use of systemic thrombolysis, surgical thrombectomy,⁶⁵⁴ or catheter-directed therapies in massive PE. In general, anticoagulation, preferably LMWH or fondaparinux, should be initiated as early as possible.⁶⁵² Oral anticoagulant therapy, preferably NOAC due to the lower bleeding risk, should be initiated, depending on post-operative renal function and bleeding risk, as early as possible for at least 3 months.⁶⁵²

Rescue thrombolytic therapy is recommended for patients with PE and haemodynamic deterioration on anticoagulation treatment in the post-operative phase, if possible, according to bleeding risk.⁶⁵² As an alternative to thrombolytic therapy for massive PE, surgical embolectomy or percutaneous catheter-directed treatment should be considered for patients with haemodynamic deterioration on anticoagulation treatment, particularly in patients with high bleeding risk.

8.6. Atrial fibrillation and other relevant arrhythmias

Post-operative AF is defined as new-onset AF in the immediate post-operative period; its incidence ranges between 2–30%, with peak incidence 2–4 days post-operatively.^{655,656}

Although many post-operative AF episodes are self-terminating and some are asymptomatic, post-operative AF has been associated with a four- to five-fold risk of AF recurrence in the 5 years following cardiac surgery, while the risk of recurrence after NCS is less well described.^{656–660} Importantly, post-operative AF is a risk factor for stroke, MI, and death compared with non-post-operative AF patients.^{656,658,661} Post-operative AF may also lead to haemodynamic instability, prolonged hospital stay, infections, renal complications, bleeding, increased in-hospital death, and greater healthcare costs.^{662–664} The essential principles of the prevention and management of post-operative AF are outlined in [Figure 20](#).

8.6.1. Prevention of post-operative atrial fibrillation

Pre-operative use of beta-blockers is associated with reduced incidence of post-operative AF,^{204,665–667} but not major adverse events such as death, stroke, or AKI.⁶⁶⁸ Importantly, in a large RCT, peri-operative metoprolol was associated with increased mortality risk.¹⁸⁵ In a meta-analysis, amiodarone (oral or i.v.) was equally effective in reducing post-operative AF as beta-blockers,²⁰⁷ whereas their combination was better than beta-blockers alone.²⁰⁸ Lower cumulative doses of amiodarone (<3000 mg) may be effective, with fewer adverse events.^{669–671}

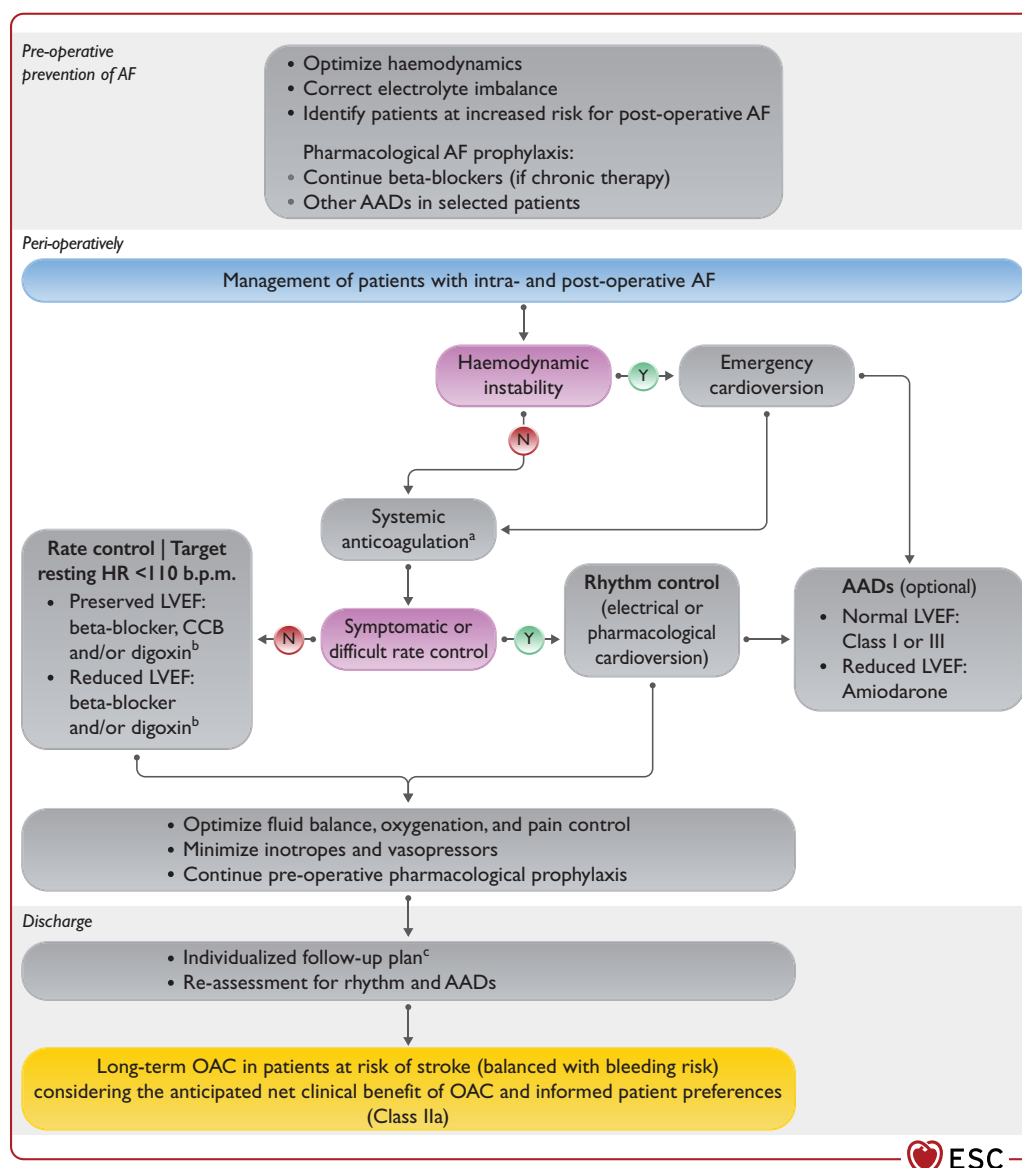

Figure 20 Prevention and management of post-operative atrial fibrillation. AAD, antiarrhythmic drug; AF, atrial fibrillation; b.p.m., beats per minute; CCB, calcium channel blocker; HR, heart rate; LVEF, left ventricular ejection fraction. N, no; Y, yes. ^aDepending on the CHA₂DS₂VASC-score, and post-operative bleeding risk. ^bIn the acute post-operative phase, unless blood pressure is high, combination of low-dose beta-blocker and loading with digoxin is preferred to avoid hypotension. ^cShould include a cardiology visit before month 3. Adapted from the 2020 ESC Guidelines on the Diagnosis and Management of Atrial Fibrillation.⁹⁹

Data for other interventions—such as statins,^{672,673} magnesium,⁶⁷⁴ sotalol,⁶⁶⁶ colchicine,⁶⁷⁵ or corticosteroids⁶⁷⁶—are not robust.^{677,678}

8.6.2. Management of post-operative atrial fibrillation

8.6.2.1. Rate and/or rhythm control

In haemodynamically unstable patients with post-operative AF, an emergent electrical or possibly pharmacological (i.e. i.v. administration of amiodarone⁶⁶⁶ or vernakalant,⁶⁷⁹ if consistent with the clinical situation) cardioversion is indicated.⁹⁹ In haemodynamically stable

patients with post-operative AF, ensuring optimal ventricular rate control during the arrhythmia is mandatory (using, for example beta-blockers or verapamil, as needed). As post-operative AF is often self-terminating, non-emergent cardioversion may not be needed. If performed in patients with AF lasting ≥48 h, non-emergency cardioversion of post-operative AF should follow the principles of pericardioversion thromboprophylaxis (that is, can be performed only after the left atrial thrombosis is excluded by TEE or postponed for 3 weeks of therapeutic OAC therapy). Of note, a RCT of patients with post-operative AF after cardiac surgery showed no net clinical

advantage of rhythm (i.e. achieving and maintenance of sinus rhythm) vs. rate control strategy.⁶⁸⁰ Therefore, rate or rhythm control treatment decisions in patients with haemodynamically stable post-operative AF should be based on patient's symptoms and shared informed treatment decision-making.⁹⁹

8.6.2.2. Prevention of atrial fibrillation-related thromboembolic complications

In all patients with post-operative AF, it should be considered to initiate therapeutic anticoagulation as soon as possible during in-hospital treatment, depending on the individual stroke risk (CHA₂DS₂-VASc) and the bleeding risk after surgery. In a large meta-analysis, patients with post-operative AF had 62% higher risk of early stroke and 37% higher risk of long-term stroke compared with patients without post-operative AF (long-term stroke rates were 2.4% in post-operative AF vs. 0.4% in patients without AF), and a 44% and 37% higher risk of early and long-term mortality, respectively.⁶⁶¹ Importantly, post-operative AF was more strongly associated with the long-term stroke risk in patients undergoing NCS (HR, 2.00; 95% CI, 1.70–2.35) than in patients undergoing cardiac surgery (HR, 1.20; 95% CI, 1.07–1.34; $P < 0.0001$).⁶⁶¹

Evidence on the effects of long-term OAC therapy for the prevention of stroke or systemic embolism in patients with post-operative AF is from observational studies.^{664,681–685} In a recent study, post-operative AF following NCS was associated with similar long-term thromboembolic risk as common, non-surgical AF, and OAC use was associated with comparable lower risk of thromboembolism and all-cause mortality in both groups (mean CHA₂DS₂-VASc-score 3.0 ± 1.7).⁶⁸⁶

Based on the available evidence, long-term OAC should be considered in all patients with post-operative AF at risk of stroke. If anticoagulation is parenterally initiated, LMWH or fondaparinux is recommended (over UFH) for most patients. Non-vitamin K antagonist oral anticoagulants should be preferred over VKA for long-term treatment. Re-evaluation of the continuation of OAC may be performed after a period of 3 months. A small RCT (ASPIRE-AF; NCT03968393) on the optimal long-term OAC use among NCS patients developing post-operative AF is ongoing.

8.7. Peri-operative stroke

With respect to NCS, peri-operative stroke has been reported in 0.08–0.70% of patients undergoing general surgery, 0.2–0.9% of patients requiring orthopaedic surgery, 0.6–0.9% of lung operations, and 0.8–3.0% of surgeries involving the peripheral vasculature.^{687,688} The associated mortality ranges from 18–26%.^{687,688} A more recent analysis of 523 059 patients undergoing NCS reported a lower incidence of peri-operative stroke (0.1%), although the occurrence of this adverse event was associated with an eight-fold increase in peri-operative mortality within 30 days, corresponding to an absolute risk increase of >20%.⁶⁸⁹ Peri-operative stroke is mainly ischaemic or cardioembolic, and AF is often the leading underlying condition. Triggers include withdrawal of anticoagulation and the hypercoagulable state related to surgery. Additional aetiologies include atheroembolism, originating from the aorta or the supra-aortic vessels, and local atherothrombosis in the presence of intracranial small vessel disease. Hypoperfusion—related to peri-operative arterial

hypotension and/or severe stenosis of the cervicocranial vessels—is an unusual cause of peri-operative stroke.⁶⁹⁰ Rarely, peri-operative stroke may be due to air, fat, or paradoxical embolisms.

In an attempt to attenuate the risk of peri-operative stroke, anti-platelet/anticoagulant treatments should be continued whenever possible throughout the peri-operative period. Alternatively, the period of drug withdrawal should be kept as short as possible, while weighting thromboembolic and haemorrhagic risks (see [Section 5.2](#)). Adequate selection of the anaesthetic technique (regional vs. neuraxial vs. general anaesthesia), prevention and treatment of AF, euglycaemic control (avoiding both hyperglycaemia and hypoglycaemia), and meticulous peri-operative control of BP may all contribute to reducing the risk of peri-operative stroke.

If post-operative stroke occurs, it must trigger immediate action: angio-CT and neurology/neurosurgical consultation with the goal to restore flow in the case of acute thrombotic occlusion.

Recommendation Table 34 — Recommendations for peri-operative cardiovascular complications

Recommendations	Class ^a	Level ^b
It is recommended to have high awareness of peri-operative CV complications, combined with surveillance for PMI in patients undergoing intermediate- or high-risk NCS. ^{41,101,109–111,118,413,636–639}	I	B
Systematic PMI work-up is recommended to identify the underlying pathophysiology and define therapy. ^{41,101,109–111,118,413,636–639}	I	B
It is recommended to treat post-operative STEMI, NSTEMI-ACS, acute HF, and tachyarrhythmias in accordance with guidelines for the non-surgical setting, after interdisciplinary discussion with the surgeon about bleeding risk. ^{98,99,171,651,652}	I	C
In patients with post-operative PE of high or intermediate clinical probability, initiation of anticoagulation is recommended without delay, while diagnostic work-up is in progress, if bleeding risk is low. ^{650,652}	I	C
Post-operative oral anticoagulation for PE is recommended to be administered for a period of at least 3 months. ^{99,650}	I	C
In patients with a post-operative indication for OAC, NOAC is generally recommended over VKA. ⁹⁹	I	A
In patients with post-operative AF after NCS, long-term OAC therapy should be considered in all patients at risk of stroke, considering the anticipated net clinical benefit of OAC therapy, and informed patient preferences. ^{99,682,683,685,686}	IIa	B
In patients with MINS and at low risk of bleeding, treatment with dabigatran 110 mg orally b.i.d. may be considered from ~1 week after NCS. ⁶⁵⁰	IIb	B

Continued

Routine use of beta-blocker for the prevention of post-operative AF in patients undergoing NCS is not recommended.^{185,201}

9. Key messages

- The occurrence of CV complications in the peri-operative phase of NCS has a dramatic impact on prognosis.
- The risk of CV complications in patients undergoing NCS is determined by patient-related factors, type of surgery or procedure, and the circumstances under which surgery takes place (elective vs. emergency procedure; local or tertiary hospital).
- Specific patient-related risk factors may be reduced by adequate pre-operative risk assessment and initiation of effective risk-reduction strategies.
- The quantification of surgical risk as low, intermediate, and high is helpful in identifying the group of patients who should most benefit from preventive, diagnostic, and therapeutic approaches to concomitant CV conditions.
- Proper selection of type and timing of the surgical procedure may reduce the risk of complications.
- It is important that patients' values, quality of life, and preferences regarding the benefits and risks of surgery are taken into consideration, and that well-informed patients are involved in the decisions. Risk should be communicated to the patient in absolute terms (e.g. 1 out of 100).
- Clinical examination, patient-reported functional capacity, and non-invasive tests represent the cornerstone of pre-operative cardiac assessment.
- Instrumental and functional cardiac examination tools should be selected in view of the surgical risk, relative diagnostic proficiency, and healthcare resource utilization and costs.
- The peri-operative evaluation of elderly patients who require elective major NCS should include frailty screening, which has proven to be an excellent predictor of unfavourable health outcomes in the older surgical population.
- Treatment of pre-existing or newly diagnosed CV conditions (e.g. coronary and peripheral vascular disease, rhythm disorders, and HF) should be individualized according to the pre-operative risk of NCS, and considering the recommendations of speciality guidelines.
- A multidisciplinary approach to evaluate whether the treatment of concomitant cardiac conditions before scheduled NCS improves peri-operative safety without unnecessary delay is encouraged.
- Efficient peri-operative management of antithrombotic therapies in patients scheduled for NCS aims to offer the potential benefit of preventing thrombotic events without excessive bleeding complications.

- It is important to clearly and concisely communicate with patients, with simple verbal and written instructions, about changes in medication in the pre- and post-operative phases.
- Management in the peri-operative phase of NCS aims to avoid haemodynamic imbalance, while ensuring sufficient cardioprotective action.
- Healthcare providers are recommended to have high awareness of peri-operative CV complications combined with surveillance for PMI in high-risk patients undergoing intermediate- or high-risk NCS.
- Routine assessment of treatment quality through specific indicators is important to document and measure the success of preventive and therapeutic strategies in patients undergoing NCS.

10. Gaps in evidence

- The age cut-off for individuals (considered to be cardiovascularly healthy) benefiting from risk stratification work-out before NCS needs to be evaluated.
- Further studies are needed to characterize outcome differences in NCS between men and women, and between different countries, in order to individualize peri-operative management and improve patient safety.
- Evidence on the additive value of cardiac biomarkers, hand-held ultrasound, problem FOCUS, and stress echocardiography for cardiac risk stratification of patients scheduled for NCS presenting with previously unknown cardiac murmur, dyspnoea, oedema, and chest pain is still lacking. The impact of FOCUS on outcomes of urgent or time-sensitive surgery needs further investigation.
- The impact of stress imaging (echocardiography or MRI) before NCS on reduction of peri-operative CV complications in non-ischaemic heart diseases needs further research.
- The role of right heart catheterization in patients with advanced HF or patients with severe pulmonary hypertension undergoing NCS is unknown.
- It is unknown whether artificial intelligence-based systems facilitate prompt detection and response to imminent adverse events in high-risk cardiac patients undergoing high-risk NCS.
- Systematic and structured research to investigate pathophysiology, causes, and time distribution of serious peri-operative arrhythmic events among patients undergoing NCS is still needed.
- Strategies for timing of pre-operative CIED control dependent on device type, urgency, and type of NCS, and risk of EMI during NCS need to be developed to ensure maximal patient safety.
- Benefit of routine myocardial revascularization of high-risk CCS patients (except left main or three-vessel CAD, reduced LV function) before elective intermediate- and high-risk NCS is not well-established.
- More evidence regarding the need for bridging of anticoagulation in patients with MHVs is needed.
- There is a lack of evidence regarding the optimal strategies before emergent or time-sensitive NCS for patients on antithrombotic treatment at high risk of thromboembolic events, including the: (i) use of extracorporeal haemoperfusion or NOAC antidotes (ongoing trial NCT04233073); (ii) use of albumin, extracorporeal haemoperfusion, or PB2452-specific antidote to antagonized ticagrelor (ongoing trial NCT04286438 for PB2452); and (iii)

premature cessation or bridging during interruption of oral P2Y₁₂-receptor inhibitors (glycoprotein IIb/IIIa receptor inhibitors or cangrelor).

- There is lack of well-powered studies to evaluate the role of platelet function testing to guide the strategy for treatment of NCS patients on antiplatelet therapy.
- Evidence regarding the need for and benefit of anticoagulation in NCS patients with post-operative AF is still lacking (ongoing ASPIRE-AF trial: NCT03968393).
- Prophylactic strategies to reduce the incidence of post-operative AF in NCS patients additional to beta-blocker maintenance in patients already on this treatment need to be evaluated.
- The optimal cardiac work-up and therapy for patients with PMI within and outside hospital settings need to be evaluated.
- Studies are needed to investigate the impact of the treatment of peri-operative hypotension on post-operative outcomes, the use of new HF drug classes (SGLT2 inhibitors and vericiguat), and the use of NSAIDs as a temporary treatment for acute post-operative pain.
- Prospective studies are needed to investigate the incremental value of anaemia algorithms and blood-sparing strategies (use of blood-sparing blood tubes) to reduce the risk of anaemia-associated adverse outcomes among CV patients undergoing NCS.

11. Sex differences

Sex and gender may significantly affect the management and outcomes of patients with specific diseases undergoing NCS. There are sex- and gender-dependent clinical phenotypes of comorbidities and risk factors, which may have an impact on peri-operative morbidity and mortality. However, there is a paucity of data specifically addressing the interplay between sex, age, and comorbidities in patients scheduled for NCS.

The pre-operative assessment before NCS might take sex into consideration, since the age-adjusted incidence of CVD is lower in

women than men, and the risk of undetected disease could therefore be lower in women. However, no data exist on sex-specific assessment strategies.

The in-hospital mortality during surgery was recently reported to be lower in women than men.^{41,691} In contrast, among 609 735 patients who underwent elective NCS between 2009 and 2016, the odds of post-operative 90 day mortality were higher among women with HF than men with HF.⁶⁹² Further studies are needed to provide more information about outcome differences between men and women in NCS.

Some studies have reported a higher risk of bleeding in women than men, but other studies could not confirm this. No trials have systematically investigated the impact of sex differences regarding efficacy and safety of continuation vs. interruption of antithrombotic therapy in patients undergoing NCS.

The prevalence of anaemia in women of reproductive age is as high as 30% (WHO Global Anaemia estimates),⁶⁹³ resulting in millions of women undergoing surgery every year despite pre-operative anaemia. Furthermore, since women have lower blood volumes and lower haemoglobin values than men, but face the same surgical blood loss as men, they are exposed to far higher risk of post-operative complications. Also, higher transfusion rates and volumes have been reported in women compared with men in elective surgery.⁶⁹⁴ It is therefore of particular importance that clinicians follow the Patient Blood Management program in women undergoing NCS. Other sex-related differences in physiology, and pharmacokinetics and pharmacodynamics of anaesthetic drugs may influence the anaesthesia plan, pain management, post-operative recovery, and patient satisfaction.

Sex differences regarding presentation, electrophysiological substrate, complications, or long-term outcomes have been reported in patients undergoing CIED implantation,^{695,696} and female sex is a well-known risk factor for stroke in patients with AF.⁶⁹⁷ However, no specific data exist that suggest sex differences in risk profile or outcomes of patients with CIEDs or arrhythmias who undergo NCS.

12. 'What to do' and 'what not to do' messages from the Guidelines

Recommendations	Class ^a	Level ^b
Recommendations for clinical risk evaluation		
In all patients scheduled for NCS, an accurate history and clinical examination are recommended.	I	C
It is recommended to perform a pre-operative risk assessment, ideally at the same time as the NCS is proposed.	I	B
If time allows, it is recommended to optimize guideline-recommended treatment of CVD and CV risk factors before NCS.	I	C
In patients with a family history of genetic cardiomyopathy, it is recommended to perform an ECG and TTE before NCS, regardless of age and symptoms.	I	C
In patients with a newly detected murmur and symptoms or signs of CVD, TTE is recommended before NCS.	I	C
In patients with a newly detected murmur suggesting clinically significant pathology, TTE is recommended before high-risk NCS.	I	C

Continued

If a patient scheduled for elective NCS has chest pain or other symptoms suggestive of undetected CAD, further diagnostic work-up before NCS is recommended.	I	C
If a patient in need of acute NCS also has chest pain or other symptoms suggestive of undetected CAD, a multidisciplinary assessment approach is recommended to choose the treatment with lowest total risk for the patient.	I	C
In patients with dyspnoea and/or peripheral oedema, an ECG and an NT-proBNP/BNP test is indicated before NCS, unless there is a certain non-cardiac explanation.	I	C
In patients with dyspnoea and/or peripheral oedema and elevated NT-proBNP/BNP, TTE is recommended before NCS.	I	C
Recommendations for patient information		
It is recommended to give patients individualized instructions for pre-operative and post-operative changes in medication, in verbal and written formats with clear and concise directions.	I	C
Recommendations for use of risk assessment tools		
In patients who have known CVD or CV risk factors (including age ≥ 65 years), or symptoms or signs suggestive of CVD it is recommended to obtain a pre-operative 12-lead ECG before intermediate- and high-risk NCS.	I	C
In patients who have known CVD, CV risk factors (including age ≥ 65 years), or symptoms suggestive of CVD it is recommended to measure hs-cTn T or hs-cTn I before intermediate- and high-risk NCS, and at 24 h and 48 h afterwards.	I	B
TTE is recommended in patients with poor functional capacity and/or high NT-proBNP/BNP, or if murmurs are detected before high-risk NCS, in order to undertake risk-reduction strategies.	I	B
Stress imaging is recommended before high-risk elective NCS in patients with poor functional capacity and high likelihood of CAD or high clinical risk.	I	B
It is recommended to use the same indications for ICA and revascularization pre-operatively as in the non-surgical setting.	I	C
In low-risk patients undergoing low- and intermediate-risk NCS, it is not recommended to routinely obtain pre-operative ECG, hs-cTn T/I, or BNP/NT-proBNP concentrations.	III	B
Routine pre-operative evaluation of LV function is not recommended.	III	C
Stress imaging is not recommended routinely before NCS.	III	C
Routine pre-operative ICA is not recommended in stable CCS patients undergoing low- and intermediate-risk NCS.	III	C
Recommendations for CV risk factors and lifestyle interventions		
Smoking cessation >4 weeks before NCS is recommended to reduce post-operative complications and mortality.	I	B
Control of CV risk factors—including blood pressure, dyslipidaemia, and diabetes—is recommended before NCS.	I	B
Recommendations for pharmacological risk-reduction strategies		
Beta-blockers		
Peri-operative continuation of beta-blockers is recommended in patients currently receiving this medication.	I	B
Routine initiation of beta-blocker peri-operatively is not recommended.	III	A
Statins		
In patients already on statins, it is recommended to continue statins during the peri-operative period.	I	B
Recommendations for peri-operative handling of antithrombotic agents		
Antiplatelets		
It is recommended to delay elective NCS until 6 months after elective PCI and 12 months after an ACS.	I	A
After elective PCI, it is recommended to delay time-sensitive NCS until a minimum of 1 month of DAPT treatment has been given.	I	B
In patients with a recent PCI scheduled for NCS, it is recommended that management of antiplatelet therapy is discussed between the surgeon, anaesthesiologist, and cardiologist.	I	C

Continued

In patients with a previous PCI, it is recommended to continue aspirin peri-operatively if the bleeding risk allows.	I	B
If interruption of P2Y ₁₂ inhibitor is indicated, it is recommended to withhold ticagrelor for 3–5 days, clopidogrel for 5 days, and prasugrel for 7 days prior to NCS.	I	B
For patients undergoing high bleeding risk surgery (e.g. intracranial, spinal neurosurgery, or vitreoretinal eye surgery), it is recommended to interrupt aspirin for at least 7 days pre-operatively.	I	C
If antiplatelet therapy has been interrupted before a surgical procedure, it is recommended to restart therapy as soon as possible (within 48 h) post-surgery, according to interdisciplinary risk assessment.	I	C
Oral anticoagulants		
When an urgent surgical intervention is required, it is recommended that NOAC therapy is immediately interrupted.	I	C
In minor bleeding risk surgery and other procedures where bleeding can easily be controlled, it is recommended to perform surgery without interruption of OAC therapy.	I	B
In non-minor bleeding risk procedures in patients using a NOAC, it is recommended to use an interruption regimen based on the NOAC compound, renal function, and bleeding risk.	I	B
In patients using NOACs, it is recommended that minor bleeding risk procedures are performed at trough levels (typically 12–24 h after last intake).	I	C
LMWH is recommended, as an alternative to UFH, for bridging in patients with MHVs and high surgical risk.	I	B
Bridging of OAC therapy is not recommended in patients with low/moderate thrombotic risk undergoing NCS.	III	B
Use of reduced-dose NOAC to attenuate the risk of post-operative bleeding is not recommended.	III	C
Recommendations for peri-operative thromboprophylaxis		
It is recommended that decisions about peri-operative thromboprophylaxis in NCS are based on individual and procedure-specific risk factors.	I	A
If thromboprophylaxis is deemed necessary, it is recommended to choose the type and duration of thromboprophylaxis (LMWH, NOAC, or fondaparinux) according to type of NCS, duration of immobilization, and patient-related factors.	I	A
Recommendations for patient blood management in NCS		
It is recommended to measure haemoglobin pre-operatively in patients scheduled for intermediate- to high-risk NCS.	I	B
It is recommended to treat anaemia in advance of NCS in order to reduce the need for RBC transfusion during NCS.	I	A
In patients undergoing surgery with expected blood loss of ≥ 500 mL, use of washed cell salvage is recommended.	I	A
It is recommended to use point-of-care diagnostics for guidance of blood component therapy, when available.	I	A
Recommendations for management of patients with specific diseases undergoing NCS		
A) Patients with CAD		
If PCI is indicated before NCS, the use of new-generation DES is recommended over BMS and balloon angioplasty.	I	A
If NCS can safely be postponed (e.g. at least 3 months), it is recommended that patients with ACS being scheduled for NCS undergo diagnostic and therapeutic interventions as recommended for ACS patients in general.	I	A
Routine myocardial revascularization before low- and intermediate-risk NCS in patients with CCS is not recommended.	III	B
B) Patients with heart failure		
In patients with suspected or known HF scheduled for high-risk NCS, it is recommended to evaluate LV function with echocardiography and measurement of NT-proBNP/BNP levels, unless this has recently been performed.	I	B
It is recommended that patients with HF undergoing NCS receive optimal medical treatment according to current ESC Guidelines.	I	A
In patients with HF undergoing NCS, it is recommended to regularly assess volume status and signs of organ perfusion.	I	C

Continued

A multidisciplinary team including VAD specialists is recommended for peri-operative management of patients with HF receiving mechanical circulatory support.	I	C
C) Patients with VHD		
Clinical and echocardiographic evaluation (if not recently performed) is recommended in all patients with known or suspected VHD who are scheduled for elective intermediate- or high-risk NCS.	I	C
AVR (SAVR or TAVI) is recommended in symptomatic patients with severe AS who are scheduled for elective intermediate- or high-risk NCS.	I	C
In patients with symptomatic severe AR or asymptomatic severe AR and LVESD >50 mm or LVESDi (LVESD/BSA) >25 mm/m ² (in patients with small body size) or resting LVEF ≤50%, valve surgery is recommended prior to elective intermediate- or high-risk NCS.	I	C
In patients with moderate-to-severe rheumatic MS and symptoms or SPAP >50 mmHg, valve intervention (percutaneous mitral commissurotomy or surgery) is recommended before elective intermediate- or high-risk NCS.	I	C
D) Patients with ACHD		
In patients with ACHD, a consultation with an ACHD specialist is recommended before intermediate- or high-risk surgery.	I	C
In patients with ACHD, it is recommended that intermediate- and high-risk elective surgery is performed in a centre with experience in the care of ACHD patients.	I	C
E) Patients with arrhythmias		
In patients with SVT controlled by medication, it is recommended that AADs are continued during the peri-operative period.	I	C
In AF patients with acute or worsening haemodynamic instability undergoing NCS, emergency electrical cardioversion is recommended.	I	B
In patients with symptomatic, monomorphic, and sustained VT associated with myocardial scar, recurring despite optimal medical therapy, ablation of arrhythmia is recommended before elective NCS.	I	B
It is recommended that patients with temporarily deactivated ICDs have continuous ECG monitoring, and during the peri-operative period are accompanied by personnel skilled in early detection and treatment of arrhythmias. In high-risk patients (e.g. pacemaker-dependant or ICD patients), or if access to the torso will be difficult during the procedure, it is recommended to place transcutaneous pacing/defibrillation pads prior to NCS.	I	C
It is recommended that all patients with CIEDs that are reprogrammed before surgery have a re-check and necessary reprogramming as soon as possible after the procedure.	I	C
It is not recommended to initiate treatment of asymptomatic PVC during NCS.	III	C
F) Patients with pulmonary hypertension		
It is recommended to continue chronic therapy for PAH in the peri-operative phase of NCS.	I	C
It is recommended that haemodynamic monitoring of patients with severe PAH continues for at least 24 h in the post-operative period.	I	C
In the case of progression of right HF in the post-operative period in patients with PAH, it is recommended that the diuretic dose be optimized and, if necessary, i.v. prostacyclin analogues be initiated under the guidance of a physician experienced in the management of PAH.	I	C
G) Patients with hypertension		
In patients with chronic hypertension undergoing elective NCS, it is recommended to avoid large peri-operative fluctuations in blood pressure, particularly hypotension, during the peri-operative period.	I	A
It is recommended to perform pre-operative screening for hypertension-mediated organ damage and CV risk factors in newly diagnosed hypertensive patients who are scheduled for elective high-risk NCS.	I	C
It is not recommended to defer NCS in patients with stage 1 or 2 hypertension.	III	C
H) Patients with PAD		
In patients with poor functional capacity or with significant risk factors or symptoms (such as moderate-to-severe angina pectoris, decompensated HF, valvular disease and significant arrhythmia), referral for cardiac work-up and optimization is recommended prior to elective surgery for PAD or AAA.	I	C
Routine referral for cardiac work-up, coronary angiography, or CPET prior to elective surgery for PAD or AAA is not recommended.	III	C

Continued

I) Patients with cerebrovascular disease		
Pre-operative carotid artery and cerebral imaging is recommended in patients with a history of TIA or stroke in the previous 6 months and who have not undergone ipsilateral revascularization.	I	C
Pre-operative routine carotid artery imaging is not recommended in patients undergoing NCS.	III	C
J) Patients with renal disease		
In patients with known risk factors (age >65 years, BMI >30 kg/m ² , diabetes, hypertension, hyperlipidaemia, CV disease, or smoking) undergoing intermediate- or high-risk NCS, it is recommended to screen for pre-operative renal disease by measuring serum creatinine and GFR.	I	C
K) Patients with obesity		
It is recommended to assess cardiorespiratory fitness to estimate peri-operative CV risk in obese patients, with particular attention to those undergoing intermediate- and high-risk NCS.	I	B
L) Patients with diabetes mellitus		
A pre-operative assessment for concomitant cardiac conditions is recommended in patients with diabetes with suspected or known CAD, and those with autonomic neuropathy, retinopathy, or renal disease and scheduled to undergo intermediate- and high-risk NCS.	I	C
In patients with diabetes or disturbed glucose metabolism, a pre-operative HbA1c is recommended, if this measurement has been not performed in the previous 3 months. In case of HbA1c ≥8.5% (≥69 mmol/mol), elective NCS should be postponed, if safe and practical.	I	B
Recommendations for peri-operative monitoring and anaesthesia		
In order to preserve optimal CV stability, it is recommended to apply goal-directed haemodynamic therapy in patients undergoing high-risk NCS.	I	A
It is recommended to avoid post-operative acute pain.	I	B
In order to minimize the risk of post-operative organ dysfunction, it is recommended to avoid an intra-operative mean arterial pressure decrease of >20% from baseline values or <60–70 mmHg for ≥10 min.	I	B
Non-aspirin NSAIDs are not recommended as first-line analgesics in patients with established or high risk of CVD.	III	B
Recommendations for treatment of post-operative cardiovascular complications		
It is recommended to have high awareness of peri-operative CV complications, combined with surveillance for PMI in patients undergoing intermediate- or high-risk NCS.	I	B
Systematic PMI work-up is recommended to identify the underlying pathophysiology and define therapy.	I	B
It is recommended to treat post-operative STEMI, NSTEMI-ACS, acute HF, and tachyarrhythmias in accordance with guidelines for the non-surgical setting, after interdisciplinary discussion with the surgeon about bleeding risk.	I	C
In patients with post-operative PE of high or intermediate clinical probability, initiation of anticoagulation is recommended without delay, while diagnostic work-up is in progress, if bleeding risk is low.	I	C
Post-operative oral anticoagulation for PE is recommended to be administered for a period of at least 3 months.	I	C
In patients with a post-operative indication for OAC, NOAC is generally recommended over VKA.	I	A
Routine use of beta-blocker for the prevention of post-operative AF in patients undergoing NCS is not recommended.	III	B

AAA, abdominal aortic aneurysm; AAD, antiarrhythmic drug; ACHD, adults with congenital heart disease; ACS, acute coronary syndrome; AF, atrial fibrillation; AR, aortic valve regurgitation; AS, aortic valve stenosis; AVR, aortic valve replacement; BMI, body mass index; BNP, B-type natriuretic peptide; BMS, bare metal stent; BSA, body surface area; CAD, coronary artery disease; CCS, chronic coronary syndrome; CIED, cardiac implantable electronic device; CPET, cardiopulmonary exercise testing; CV, cardiovascular; CVD, cardiovascular disease; DAPT, dual antiplatelet therapy; DES, drug-eluting stent; ECG, electrocardiogram; ESC, European Society of Cardiology; GFR, glomerular filtration rate; HbA1c, glycated haemoglobin; HF, heart failure; hs-cTn, high-sensitivity cardiac troponin; ICA, invasive coronary angiography; ICD, implantable cardioverter-defibrillator; LMWH, low molecular weight heparin; LV, left ventricular; LVEF, left ventricular ejection fraction; LVESD, left ventricular end-systolic diameter; LVESDi, left ventricular end-systolic dimension index; MHV, mechanical heart valve; MS, mitral valve stenosis; NCS, non-cardiac surgery; NOAC, non-vitamin K antagonist oral anticoagulant; NSAID, non-steroidal anti-inflammatory drug; NSTEMI-ACS, non-ST-segment elevation acute coronary syndrome; NT-proBNP, N-terminal pro-B-type natriuretic peptide; OAC, oral anticoagulant; PAD, peripheral artery disease; PAH, pulmonary arterial hypertension; PCI, percutaneous coronary intervention; PE, pulmonary embolism; PMI, peri-operative myocardial infarction/injury; PVC, premature ventricular contractions; RBC, red blood cell; SAVR, surgical aortic valve replacement; SPAP, systolic pulmonary artery pressure; STEMI, ST-segment elevation myocardial infarction; SVT, supraventricular tachycardia; TAVI, transcatheter aortic valve implantation; TIA, transient ischaemic attack; TTE, transthoracic echocardiography; UFH, unfractionated heparin; VAD, ventricular assist device; VHD, valvular heart disease; VKA, vitamin K antagonist; VT, ventricular tachycardia.

13. Quality indicators

Quality indicators (QIs) are tools that may be used to evaluate care quality, including structural, process, and outcomes of care.⁶⁹⁸ They may also serve as a mechanism for enhancing adherence to guideline recommendations, through associated quality improvement initiatives and the benchmarking of care providers.^{699,700} As such, the role of QIs in improving care and outcomes for CV disease is increasingly being recognized by healthcare authorities, professional organizations, payers, and the public.⁶⁹⁸

The ESC understands the need for measuring and reporting quality and outcomes of CV care and has established methods for the development of the ESC QIs for the quantification of care and outcomes for CV diseases.⁶⁹⁸ To date, the ESC has developed QI suites for a number of CV diseases^{701–703} and embedded these in respective ESC Clinical Practice Guidelines (2020 ESC Guidelines for the diagnosis and management of atrial fibrillation; 2021 ESC Guidelines for the diagnosis and treatment of acute and chronic heart failure; and 2021 ESC Guidelines on cardiac pacing and cardiac resynchronization therapy).^{99,412,481,704} Furthermore, the ESC aims to integrate its QIs with clinical registries such as the EURObservational Research Programme (EORP) and the European Unified Registries On Heart Care

Evaluation and Randomized Trials (EuroHeart) project⁷⁰⁵ to provide 'real-world' data about the patterns and outcomes of care for CV disease across Europe.

In parallel with the writing of this Clinical Practice Guideline document, a process has been initiated to develop QIs for patients undergoing NCS using the ESC methodology and through collaboration with patient representatives and domain experts. Such QIs may be used for evaluation of the quality of care for this group of patients and enable capture of important aspects of care delivery. The QIs, alongside their measurement specifications and development process, will be published in a separate paper.

14. Central illustration

There is a complex interplay between the intrinsic risk of surgery and the patient-related risk of peri-operative CV complications. This latter risk depends on the baseline general and CV status of patients scheduled for NCS. For each patient, the proper quantification and communication of the surgical risk require close cooperation between cardiologists, surgeons, anaesthesiologists, general practitioners, and other healthcare providers (Figure 21).

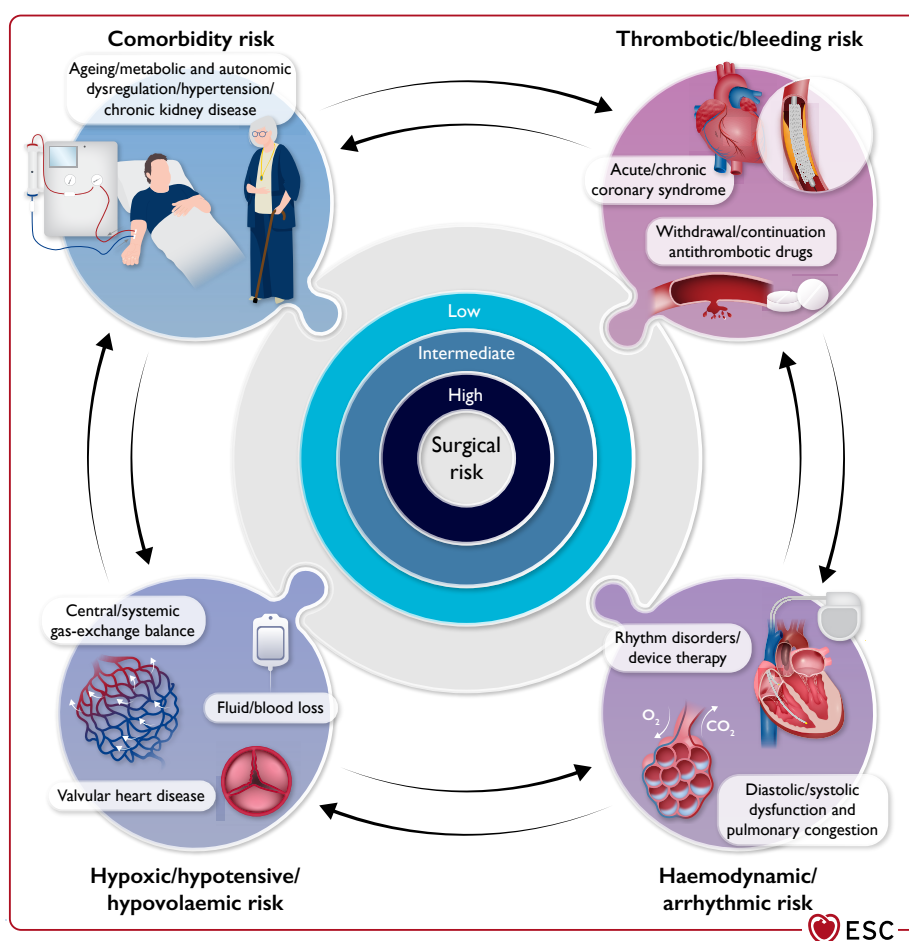

Figure 21 Central illustration: the complex interplay between the intrinsic risk of surgery and the patient risk of peri-operative cardiovascular complications.

15. Supplementary data

Supplementary data is available at *European Heart Journal* online.

16. Data availability statement

No new data were generated or analysed in support of this research.

17. Author information

Author/Task Force Member Affiliations: **Salvatore Cassese**, Klinik für Herz- und Kreislauferkrankungen, Deutsches Herzzentrum München, Munich, Germany; **Trygve S. Hall**, Department of Cardiology, Oslo University Hospital, Ullevål, Oslo, Norway; **Magdy Abdelhamid**, Cardiology Department, Faculty of Medicine, Kase Al Ainy, Cairo University, Cairo, Egypt; **Emanuele Barbato**, Advanced Biomedical Sciences, University Federico II, Naples, Italy, Cardiovascular Center Aalst, OLV Hospital, Aalst, Belgium; **Stefan De Hert**, Department of Anesthesiology and Perioperative Medicine, Ghent University Hospital/Ghent University, Ghent, Belgium; **Tobias Geisler**, Department of Cardiology and Angiology, University Hospital Tübingen, Tübingen, Germany; **Lynne Hinterbuchner**, Department of Cardiology, Clinic of Internal Medicine II, Paracelsus Medical University of Salzburg, Salzburg, Austria; **Borja Ibanez**, Clinical Research Department, Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid, Spain, Cardiology Department, Fundación Jiménez Díaz Hospital, Madrid, Spain, CIBERCV Centro Investigacion Biomedica en Red, Madrid, Spain; **Ingrid de Laval** (Sweden), ESC Patient Forum, Sophia Antipolis, France; **Radosław Lenarczyk**, Department of Cardiology, Congenital Heart Diseases and Electrotherapy, The Medical University of Silesia, Division of Medical Sciences in Zabrze, Zabrze, Poland, Silesian Center for Heart Disease, Zabrze, Poland; **Ulrich R.
